## INDEX.

REMOTE STORAGE

**A**BERDEEN Hammermen's Exhibition, 295  
 Absolute resistance of mercury, by R. T. Glazebrooke, 340  
 Accident at Blackpool, 70  
 " Brighton electric light wire, 16  
 " electric fire, at Paris, 367  
 " Fatal electric tram, 355  
 " Florence electric tram, 383  
 " at a Paris lighting station, 495  
 Accidents, Fatal electrical, 272  
 " from electric currents, Prevention of, 287  
 " Railway, for 1889, 353  
 Account of some experiments upon the application of electrical endosmose to the treatment of gouty concretion, by Thos. A. Edison, 213  
 Accumulator explosions, 498, 529  
 " traction, 5, 56, 703  
 " " in Australia, Failure of, 626  
 " " Cost of, 37, 271  
 " " in Paris, 591  
 " trams, 320  
 Accumulators, Management of, Part IV., 8  
 " in telegraphy, 271  
 " Tudor, 463  
 Accurate measurements of low resistances 12  
 Acknowledgment, 237  
 Action of lightning on the human organism, 77  
 Adjustable telephone transmitter, 87  
 Adoption of the electric light at Barnsley, 127  
 Advance in rubber, 401  
 Advantages of technical education, 431  
 Advertising, Electricity and, 243  
 Advertisement—*fin de Siècle*, 575  
 Advice gratis, 528  
 African telegraph service, 368  
 Agricultural show, Royal, 21  
 Air condensers of the British Association, by R. T. Glazebrook, 391  
 " Electrical conductivity of, and the formation of ozone, 60  
 Alloys of nickel and iron magnets, Properties of, 163  
 Alternate current machines, Method of synchronising, 148  
 " " motor, 76  
 " currents, Anti-effective copper in parallel or coiled conductors for, by Sir W. Thomson, 308  
 " " in parallel conductors of homogeneous or heterogeneous substance, by Sir W. Thomson, 314  
 Alternating v. continuous currents in relation to the human body, by H. N. Lawrence and A. Harries, 301, 344  
 " current experiment, 242  
 " lighting in Baltimore, 530  
 " " motor, 76  
 " currents, doomed, 216  
 " Properties of, 640  
 " Some points about, 120  
 " motors, Tesla's new, 207  
 " system in Russia, 45  
 " transformer system in South America, 611

Alternative path experiments, by Dr. Oliver Lodge, 90  
 " " Prof. Lodge's communication, &c., by S.A. Varley, 122, 172  
 Alternator, Elihu Thomson's new, 176  
 " An historical, 210  
 " Yet another, 231  
 Aluminium Company, 296  
 Amalgams, Certain behaviour of, 623  
 Amendment, The Hopkinson, 259  
 America, Taking the lead of, 30  
 " Manufacture of cables in, 158  
 " (North) electric lighting statistics, 217  
 " Strike in, 241  
 " Western Gas Association of, 45  
 American Association for the Advancement of Science, 336  
 " company dividend, 721  
 " eagle, 95  
 " on the wing, 641  
 " electric transit statistics, 334  
 " Patent Office, 159  
 " promptness, 187  
 " theatre lighting, 270  
 Americans, What they say, 158  
 Annealing of copper, The, 272  
 " " by G. Wickoff Cummings, 277  
 Another fatal shock, 431  
 Anticosti cable, 400  
 Apparatus for examining the variation of electromotive force with temperature, 521  
 Applied classics, 658  
 Appointment, Mr. A. R. Bennett, 156, 186  
 " Mr. E. A. O'Keeffe, B.E., 334  
 Arc lamp tablets, Wade's patent, 369  
 " lamps, Improvement in, 115  
 " New, 272  
 " The efficiency of, 355  
 " with alternating currents, 496  
 " light and battery carbons, 14  
 " carbons, Life and efficiency of, 164  
 " trimming, Cost of, 186  
 " Musical Society, 528  
 Aron meter, 690  
 Artificial light of the future, by Prof. E. L. Nichols, 705  
 Artillery practice, Electricity in, 296  
 Asbestos-faced valve, 591  
 As old as the hills, 59  
 Austin's Infant dynamo, 97  
 " "Novel" hand dynamo, 335  
 Australia, Electricity in, 402  
 Australian cable, 334  
 " news, 90  
 Austria, Progress of telegraphy in, 263  
 Austro-Hungary, Communications from, 89, 211, 290  
 Automatic fire alarms, 721  
 Award, M. Ducretet, 216  
 " Messrs. Lacombe, 561  
 Awards, Edinburgh Exhibition, 186, 231  
 Ayrton, Prof., on chemistry of secondary cells, 650, 693, 714, 759

**B.** A. ethics, 289  
 Bahamas, The, 400  
 Bailey, F., on electric lighting progress in London, 747  
 " Theo. P., on electric railways, 781  
 Ballooning, electricity and, 218  
 Barber Starkey, W. J. S., on secondary cells, 304

Barnet, lighting, 43  
 Barnsley and electric lighting, 76, 94, 127, 333  
 Base ball reporting, 401  
 Bath chair, electric, 401  
 " electric light at, 103, 260  
 Batteries, dry, 368  
 " secondary, 69, 85  
 Battery, new primary, 186  
 " primary, 4  
 " voltaic, with iron electrode in pure water, 214  
 " Vaughan Sherrin, 384  
 Belgian Society of Electricians, 788  
 Bell, Dr. Louis, on the progress of electrical traction, 53  
 Belting, 272  
 Belt strength, by R. Grimshaw, 8  
 Belts, electric, 187  
 " Beneficent murder," 217  
 Bennett, A. R., 156, 186, 244  
 Benwell murder and the telephone, 368  
 Berlin lighting, 69, 366  
 " new central station, 127  
 " Warsaw telephone, 127  
 Berliner's gramophone, 433  
 Bermuda cable, 70  
 Bermudas, electric light wanted in, 244  
 " Halifax cable, 244, 248  
 Bidwell, Sheldford, on selenium cells, 792  
 Bi-metallic conductors, 216  
 Binswanger's patent improved "H.I." cut-outs, 243  
 Birkenhead Electric Lighting Bill, 44  
 Birmingham Bristol Road electric tramway, 92  
 " Electric light at, 260  
 " Electric traction at, 95  
 Blackpool, fatal accident at, 70  
 Blasting by electricity, 336  
 Bleaching by electricity, 260  
 Board of Trade, proceedings of, 145  
 " regulations, 71  
 Boilers, 753  
 Bois, Du, On magnetic circuits, 421  
 Bombay, Electric light at, 116  
 Borkum Island, intended electric light on, 96  
 Boston electrical trams, 334  
 Bourdeaux, Jno, 41  
 Bradford Corporation lighting, 333  
 Bradford free library, 591  
 Braul's experiments on the variations of conductivity, 770  
 Breaking telephone insulators, 68  
 Bremen electric tramway, 45, 209  
 Breslau, lighting in, 127  
 Bridlington electric light, 68  
 Brighton Council and the Brighton and Hove Electric Lighting Company, 787  
 " electric light at, 68  
 " " wire accident, 16  
 " Hotel Métropole, 96, 156  
 " lighting, 45  
 Bristol, connoisseurs from, 69  
 " and the electric light, 156, 295  
 " University College, 273  
 British Insulated Wire Company, 559  
 " cable, 703  
 Britannia Company, 334  
 BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, LEEDS, 1890:—  
 Abstract of address, by Sir F. Abel, 281  
 Alternate currents in parallel conductors of homogeneous or heterogeneous substances, by Sir William Thomson, 314

BRITISH ASSOCIATION—*continued.*

- Alternating *versus* continuous currents in relation to the human body, by H. N. Lawrence and A. Harries, 301
- Anti-effective copper in parallel conductors, by Sir William Thomson, 308
- Character of steel used for permanent magnets, by W. H. Preece, 305
- Compensation of alternating current meters, by J. Swinburne, 506
- Column printing telegraph, by F. Higgins, 348
- Discussion on the report of the committee on standards, 426
- Discussion on alternating currents in relation to the human body and fire insurance rules, 344
- „ on Testing iron, 346
- Effect of oxidation on the magnetic properties of manganese steel, by O. T. O'Shea, 346
- Electric lighting and fire insurance rules, by Wilson Hartnell, 299
- Electrostatic force between conductors conveying steady or transient currents, by Dr. Oliver Lodge, 426
- Experiments to determine wave velocity in certain dielectrics, by F. T. Troughton, 526
- Form of submarine cables for long distance telephony, by W. H. Preece, 309
- Illustration of contact electricity presented by the multicellular electrometer, by Sir William Thomson, 303
- Lineff electric tramway, by Gisbert Kapp, 347
- Notes on high vacua, by J. Swinburne, 505
- Recent determinations of the absolute resistance of mercury, by R. T. Glazebrook, 340
- Secondary cells, by W. J. S. Barber Starkey, 304
- Suggestions towards the determination of the ohm, by J. V. Jones, 311
- Testing iron, by J. Swinburne and W. F. Bourne, 345
- The air condensers of, by R. T. Glazebrook, 391
- Thomson's, Sir W., new electricity meter, 423
- Value of certain standard resistance coils, by R. T. Glazebrook, 424
- Broker's view, 703
- Bromley electric lighting, 156
- Brooks, David, on liquid insulation for underground conductors, 366
- Browett, Lindley & Co., Limited, 754
- Brush v. King, Brown and Co., 143
- Buda-Pest electric tramway, 58
- Buller, Jobson & Co., Limited, 402
- Bull ring of the Rue Pergolese, 585
- Burnand's new burlesque, 5
- Burton backward, 294
- Business extension, 295, 465
- „ men interviewed, 5
- „ mention, 464

## CABLE AND CABLES—

- Account of a cable expedition, 431
- across the North Sea, 658
- Another Franco-Danish, 625
- Anticosti, 400, 432
- Argentine, 528
- „ European, 617
- Australian, 334, 668
- Bahamas, 511
- Bermuda, 70
- Bermudas-Halifax, 244, 248
- Channel telephone, 95
- English and French submarine, 157
- First Atlantic, 561
- French submarine, 4, 625
- „ manufactory of, 690
- Halifax and Bermuda, 15, 43
- „ company, 70, 590
- interruption, 367
- „ The late, 272
- Interruptions and repairs to submarine, 212, 271
- Laying, 243, 447
- „ made easy, 176
- „ story, 368
- Magdalen Islands, 400
- Manufacture of in America, 158

CABLE AND CABLES—*continued.*

- Manufacture in Italy, 16
- New, 626
- „ between Chili and Peru, 464
- „ telegraph, 690
- Ocean and electric railways, by T. D. Lockwood,
- Pacific, 464, 587, 592, 655, 787
- Quick service, 593
- rates, New Zealand, 269
- Recent interruptions and repairs to, 214, 431, 528, 720
- ships, 296
- Spain and Morocco, 294
- Spanish-African, 561
- „ Atlantic, again, 214
- „ Morocco, 593
- „ (New), 156, 214, 243, 431
- Submarine, 217
- „ The form of for long distance telephony, by W. H. Preece, 309
- subsidy, 722
- telegraphic, Earthquake shocks and, 70
- Telephone, 407
- „ Laying a, 401
- testing, 187, 216, 230, 242
- Tory Island, 14, 69, 243, 272
- Underground, 721
- wanted in Paraguay, 590
- West India, 288
- „ New, 493, 721
- Western Union, 95
- Camp, A. J. de, on the value of detail in the care and labour of electric light stations, 377
- Canadian installations, Particulars of, 23
- Canal traffic, 625
- Candid statement, 671
- Candle power, 384
- Canterbury lighting, 68, 214
- Canvas and rubber and leather belts, Comparative tests of, by Samuel Weber, 266
- Capital punishment by electricity, 145, 294
- Carbon lamps, Manufacture of double, 15
- „ resistance, Variation of, 241
- „ shields for arc lamps, 655
- Carbons, Mahla's, 70
- Car companies at Chicago, 215
- Cardiff lighting, 94
- Catalogue, 626
- Carhart, Prof. H. S., Some points about alternating currents, 120
- „ „ „ On electricity at the American Association, 339
- Carré, M. Ferdinand, 201
- Castleford and street lighting, 400
- Cataphoric medication, 230
- Cathcart and Peto, 44
- Cathedral, Milan, 127
- Causes of death by electricity, Further notes upon, by Dr. E. Tatum, 121
- Cells, Creeping on, 401
- „ Secondary, 288
- Censorship of the Board of Trade, 671
- Census taking, Electrical, 340
- Central Institution students, 463
- „ London Railway Bill, 69
- CENTRAL STATION—
- as an investment, 574
- Berlin, 127
- Companion, 188
- Copenhagen, 548
- Dynamo in, 214
- New station in Vienna, 690
- Notes on central station electric lighting, by C. H. Yeaman, 619
- „ Private, 71
- Reichenhall, 179
- Sardinia Street station, 491
- Seville, 441
- The Troyes, 60
- Verona, 157
- vertical side-by-side compound high-speed engine, 7
- Century, The events of 87
- Chair of Industrial Electricity at the Paris Conservatoire of Arts and Sciences, 590
- Challenge, A, 30
- Chance for inventors, 271
- Chassagny and Abraham, H., on researches in thermo-electricity, 769

- Chatelier, Le H., on electrical resistance of metals, 454
- Character of steel used for permanent magnets, by W. H. Preece, 305, 346
- Charterhouse Science and Art Schools and Literary Institute, 335
- Cheap transport, 293
- Chelsea electric lighting, 369
- „ Electricity Supply Company and the Vestry, 788
- Chemical and electric works, Kilmarnock, 70
- Chemistry of secondary cells, by W. E. Ayerton, 650, 693, 714
- „ „ storage batteries, Frankland's researches on, 204
- Chicago car companies, 215
- China and Japan telegraphs, 187
- Chinese Telegraph Convention, 367
- Chin-Lushai expedition, The telegraph in, 336
- Chiswick, Electric traction at, 156
- Choosing a rubber belt, by R. Grimshaw, 172
- Church lighting, 176, 185, 241, 333
- „ service by telephone, 401
- Cigar arc lighter, 186
- Circuits, Telephone troubles from outside, 87
- City electric lighting, 216
- „ and Guilds Institute, 186, 368

## CITY NOTES—

- Allgemeine Electricitäts Gesellschaft (Berlin), 46, 629
- American Bell Telephone Company, 19
- Anglo-American Telegraph Company, 100, 130, 160, 403, 591
- Automatic Electric Railway Signal Company, 19
- Bankers' and Merchants' Telegraph Company, 275
- Berlin General Electricity Company, 161
- Birmingham Tramway Company, 189
- Blackpool Electric Tramway Company, 629, 660
- Brazilian Submarine Telegraph Company, 435, 467, 500
- Brush Electrical Engineering Company, 275, 297
- Byng Telephone Company, 161
- Chemical Carbon Company, 100
- Chili Telephone Company, 134, 190
- City and South of London Railway Company, 160, 190
- Crompton and Co., 74, 98
- Commercial Cable Company, 299, 596, 753
- Consolidated Telephone Construction and Maintenance Company, 500
- Cuba Submarine Telegraph Company, 100, 161
- Direct Spanish Telegraph Company, 337, 370, 403
- „ United States Cable Company, 74, 98, 131, 467
- Eastern Extension, Australasia, and China Telegraph Company, 19, 100, 370, 629
- „ Telegraph Company, 46, 72, 403, 499
- Edison and Swan United Electric Light Company, 74, 100, 130
- „ Electric Illuminating Company, 74
- Electric Construction Corporation, 191, 245, 629, 659, 702, 724
- „ and General Investment Company, 337
- Electrical Engineering Corporation, 531
- Elmore copper for America, 596
- Elmore's Foreign and Colonial Patent Copper Depositing Company, 629
- „ Patent Copper Depositing Companies, 100, 130, 134, 161, 370, 430
- „ Wire Manufacturing Company, 73, 191, 370
- European Electric Welding Company, 191
- Fowler Waring Cable Company, 723, 724
- Franco-Russian Company, 435
- General Electric Company, 219
- „ Power and Traction Company, 370, 754
- Globe Telegraph and Trust Company, 74, 130, 370
- „ Electrical and Engineering Company, 755

CITY NOTES.—*continued.*

Greenwood and Batley, Limited, 757  
 Gülcher (New) Electric Light and Power Company, 725, 756  
 Hartlepool Gas and Water Company, 275  
 India-Rubber Estates Company, 46  
 " Gutta-Percha and Telegraph Works Company, 19, 46  
 Indo-European Telegraph Company, 531  
 International Okonite Company, 435  
 Irish Electric Light Company, 19

 City and South London Railway, 464, 530, 542, 554, 594, 722, 755, 788  
 Civilian electrician in modern war, by Lieut. Bradley Fiske, 577, 593  
 Claims of primary batteries, 216  
 Clear off the track, 575  
 Club, The Whitehall, 70  
 Coal mining equipment, Electric, 268  
 Coatbridge lighting, 96  
 Cockburn, A. C., 271

Coefficient of self-induction, 590  
 Coffin, Dr., On electric welding process, 754  
 Columbian Exhibition, 96  
 Colomb, Admiral, to be rewarded, 16  
 Coloured insulators, 561  
 Column printing telegraph, by F. Higgins, 348  
 Combination electric switch, by Lieut. Saml. Rodman, 576  
 "Coming Men," 659  
 Communications from Austro-Hungary, 89, 211, 290, 440, 576, 644  
 " from Italy, 761  
 Communication with Turks Island, 528  
 Companies' meetings, 272  
 Companion, Central Station, 188  
 Comparative tests of leather and canvas-rubber belts, by Saml. Webber, 266  
 Comparison of a platinum thermometer with some mercury thermometers at low temperatures, by E. H. Griffiths, M.A., 363  
 Competition, National Art, 128  
 Compound winding case, 70, 176, 188, 296  
 " dynamo machines, 104  
 Compressed air for the transmission of power, 234  
 Condensers (air) of the British Association, by R. T. Glazebrook, 391  
 Conductors, Bi-metallic, 216  
 " Economy in systems of distribution, 712, 740  
 " Lightning, connecting to gas and water pipes, by Prof. L. Weber, 90  
 Conduits, Electric railway, 129  
 Congo, The telephone on the, 335  
 Connoisseurs at Bristol, 69  
 Constant current dynamos, New regulation for, 91  
 Consulting electricians, 129  
 Contact electricity presented by the multicellular electro-meter, by Sir W. Thomson, 303  
 Continent, Gas and electric lighting on, 129  
 Continental Edison Company, 233  
 " lighting, 367  
 Contracts by telephone, 273  
 Contribution to the molecular theory of induced magnetism, by J. A. Ewing, 386  
 Convention, Chinese telegraph, 367  
 Copper, 274, 447, 464  
 " The annealing of, 272  
 " " by G. Wyckoff Cummins, 277  
 " companies, Elmore's, 260  
 " manufacturing industry, A revolution in the, 381  
 " The specific resistance of, by T. C. Fitzpatrick, 357  
 Corporation of Salford v. Lever, 14  
 Correction, 186, 273, 432, 562, 721, 755

## CORRESPONDENCE—

Accumulator management, by B. B., 508  
 " management, by W. J. S. Barber Starkey, 539  
 " explosions, by H. Edmunds, 508  
 " explosions, by A. A. C. Swinton, 539  
 " explosions, by J. Hunter, 539  
 " explosions, by Lyndhurst, 540  
 " explosions, by F. W. Cooke, 572  
 Accurate measurement of low resistance, by O. Berend & Co., 172  
 Alternating current meters, by Arthur Wright, 442  
 " current meters, by Nikola Tesla, 634  
 An answer of thanks, by James Johnstone, 352  
 Bath installation, The, by Charles Powell, 380  
 Bremen electric tramway, Thomson-Houston International Electric Company, 409  
 British Insulated Wire Company, by C. H. Yeaman, 604, 796  
 " Wire Company, by J. B. Atherton, 604

CORRESPONDENCE.—*continued.*

## THE INTERNATIONAL OKONITE COM- PANY, LIMITED.

"CERTAINLY the person who is able to rate at their true worth the statements in prospectuses is very rare. We have no time to go to Vancouver's Island to learn whether the coal from there has the alleged percentage of carbon, and we should be no wiser if we went. We are not accountants; we must take for granted as true the assertion that the output or turnover was such-and-such, and the reserve fund is so-and-so. No one questions all this, so far as direct positive averments are concerned. . . . There is the cleverly drafted, skilfully baited prospectus; no one can lay a finger upon a phrase therein personally pledging anyone concerned in issuing it. . . . Anybody who cares to inspect contracts, more or less intelligible, . . . may find out the facts for himself. Everyone knows that there will be no such examination. Subscriptions will be made solely on the strength of the names of the directors or promoters. They are the bait, and they know it."

We quote the above from an article entitled "Limited Liability in Morals," in our political and critical contemporary, the *Speaker*. To those interested in the subject we can recommend the perusal of the entire article, which appeared in the issue of Saturday last.

On Monday was published the prospectus of the International Okonite Company, promoted by Woodhouse and Rawson United, Limited, one of whose directors (Samuel Pope, Esq., Q.C.) is on the board. The other directors are Lord Greville (chairman of Eastman's, Limited, a recent Stock Exchange success which it is of value to mention); Sir Alexander Armstrong; H. Dobree, Esq.; Major Charles Jones and Sir William Davies; Sir Rawson Rawson and Lord Aberdare being trustees.

At the head of the prospectus is a statement of the average dividends paid for the past 6 and 13 years respectively by, and the present market price of the shares of, the Silvertown Company and the Tele-

graph Construction and Maintenance Company. The capital is £340,000 in shares, and £100,000 in debentures, and the object is to purchase and extend the businesses of the Okonite Company, of New York, and Messrs. Shaw and Connolly, of Manchester. Okonite is described as "a valuable compound prepared and applied by special processes," and there is a statement of the manifold virtues which the Okonite Company claim for their products. The prospectus, as advertised, does not detail the reports of Sir Wm. Thomson and Dr. Hopkinson; but it states that it is "*mainly* on account of the high qualities of okonite wires and cables that they have consented to accept the responsible post of consulting engineers to the company." There are evidently other considerations, but they take quite a secondary place.

Then follows a description of the American factory, with particulars of its water-power and rental therefor; an accountant's report, which shows that the company has done a very satisfactory business for the past three years, with a remarkable increase in the last one. A momentary divergence takes us from accomplished facts into the region of "estimates," to which we need not now refer, as we have a larger instalment later. Mr. F. L. Rawson, having been sent out by the vendor company, reports that from "information he obtained," and persons he saw, he "became convinced that the business was of high class, the works and products excellent, and those connected with the company were men of probity and commercial standing"—a gratuitous testimonial which we hope they will appreciate.

The English business is acquired on the guarantee that the books, "when examined by the company's auditors shall give the results stated by" the proprietors to the directors, *i.e.*, over £4,000 last year, and for this year at the rate of £6,000 per annum. Considering the detail with which the American profits are set forth, and the certificate thereon, there is something wanting in the statement relating to the English business. "The company's auditors" took steamer for New York,

or the New York books were sent to London. Why couldn't they take the train to Manchester, or the Manchester books be sent to them? What is the nature of the "guarantee?"

There are the usual baits of probable subsidiary companies, and powers to pay interim dividends.

After particulars of management, its complicated remuneration, and a statement that the present holders of the business have agreed to retain £100,000 worth of shares for four (with such prospects the wonder is they do not make it forty) years, there is given in considerable detail an estimate of future profits, which "is based on the information supplied by the Okonite Company of America, and Messrs. Shaw and Connolly, to the directors." Estimates are given separately for the present and three following years, according to which the debentures are always to get their 6 per cent., the preference shares their 8 per cent., and the ordinary shares their 15 per cent., with occasional bonuses in addition for everybody but the poor debenture holders, leaving surpluses of a very improving character, which are conveniently summarised, and go towards an extra bonus. We think this extra bonus sufficiently shadowy to render it unnecessary for us to set it forth in detail. The purchase price has been fixed at £224,990—£113,330 in shares, £33,300 in debenture, and £78,360 in cash. The average profits of the American business for the three years is £14,000 per annum. There is no material for an average of the English business, but taking the figures "guaranteed" for last year's profits (£4,000), we have £18,000 per annum for the profits of the combined businesses. The company purchases these at the rate of  $4\frac{1}{3}$  years' purchase in *cash*,  $1\frac{5}{8}$  years' purchase in *debentures*, and nearly  $6\frac{1}{3}$  years' purchase in *shares*; altogether about  $12\frac{1}{2}$  years' purchase. Or, if we do not take an average, the purchase price is at the rate of eight years' purchase on the business of 1889.

It seems to us the directors might have omitted some of the matter in the prospectus in order to find room for expert testimony that  $12\frac{1}{2}$  years' purchase on the average of three years' business, or eight years' purchase on one exceptional year's business, is a fair and reasonable rate; or they might have profitably stated that if they were buying the businesses in their private capacity they would have jumped at the opportunity.

We do not overlook the fact that the purchase includes such tangible assets as buildings and machinery, as well as such intangible ones as processes and goodwill. We should have preferred to separate the wheat from the chaff, but the prospectus does not give us an opportunity of doing so. We have not deducted anything on account of patents, though the new company purposes providing £1,000 a year for depreciation. No details are given regarding these patents, so that we cannot form any idea whether the American Company is right in deducting nothing, or the English Company making unnecessary sacrifices in deducting too much.

Under the circumstances, it may be matter for regret that over £110,000 is left for "working" capital.

The accountants "examine and report," the experts "report," Mr. Rawson "becomes convinced," the Okonite Company "claim," Messrs. Shaw and Connolly "guarantee," and "estimates are based on information." With all this, however, are the directors free from responsibility? We think not. What is the general effect produced on the average investor unfamiliar with electrical enterprises by a perusal of the prospectus? Being told that the India-rubber Company has paid an average of 13 per cent. during the last six years, is he expected to enquire whether it has always paid that munificent dividend? When it is stated that the Telegraph Construction and Maintenance Company has paid 20 per cent. per annum for a number of years, is he to assume that the Okonite Company starts with the same valuable connection? Do the directors wish him to understand that the Okonite Company either can or will be engaged in a similar business to either of these companies? When an estimate of future profits is given in such detail as to occupy, more or less, 100 lines in the *Times* newspaper, and contains the important "Note" that "the calculations of dollars into pounds are made at \$4.85 to the £ sterling," is the intelligent Briton expected to arrive at the conclusion that the estimate is purely imaginary and absolutely valueless, or is he expected to be impressed with "15 per cent.?"

The promoters and directors cannot shift the responsibility for the publication of such an estimate and the inference to be drawn from it. Mr. Samuel Pope, Q.C., in his capacity of Chairman of the English Association of American Bond and Shareholders, has surely had some experience of disappointed hopes in limited companies. Sir Alexander Armstrong has been connected with some electrical concerns. He might perhaps give his colleagues some information bearing on the question of estimates and results—the relation of prospectus to performance. The directors, as a body, must be aware that businesses have their ups and downs. The Okonite Company has had its ups—very good ones. Is it absolutely impossible that there should be an alteration in the direction of the curve? Is it possible that the sale to, and management by, an English company may in any degree affect the continued successful working of the American business?

We are not concerned with the quality of the material itself. The development of the American company would imply that either it must have some considerable merit or the business have been well managed—perhaps both.

Placed upon the market in a business-like manner, we would have heartily welcomed Okonite. As it is, we can but condole with it in its misfortunes. To be expected to pay a dividend on a capital of £440,000, with an expensive organisation and ornamental directors, would appal many better substances than Okonite. We hope it may be equal to the occasion, and that our fears of disaster for the company may be mistaken.

We think that the shareholders of Woodhouse and Rawson should recognise the value of the permanent

staff in carrying on what is generally understood to be its "legitimate" business, for we do not see how the directors and managers can well spare for details any of the time which must needs be occupied in the promotion of companies from copper-deposition to co-operative stores. With the interest of the electrical trades at heart, we would suggest to them the selection of one or other *rôle*—electrical supplies or company promotion. We fear they will find that the combination is not consistent with sound business on a permanent basis. If they should decide to give up the company promotion department, we should not regret it. We have no desire that electrical affairs should be placed before the public in a form which is at least misleading, and which must almost inevitably produce disappointment to the investor and detriment to the electrical profession.

A correspondent sends us the following :—

"Full information is given in the prospectus as to the business of the two concerns, and the opinion of an expert is quoted as to the desirability of acquiring the American business with the view to its extension by means of a company. The expert who went over to the States to examine into the value of the manufacture of *okonite* and the business of the concern is, I learn from the prospectus, the managing director of the company who are now promoting the new undertaking.

"The profits of both undertakings are given during the past few years, and the estimates of the future profits are given on a considerably-increased scale, and the dividends to be derived are fairly compatible with the case if *no other wire* but *okonite* was ever used. There is one point in the estimates of the future profits I should like to draw attention to, as it has an important bearing upon the actual amount which should be realised. In the prospectus it states, 'there is every reason to believe that in the near future, when *okonite* covered wire can be obtained in England for home consumption and export to other countries, the profits from the English branch will equal, if not exceed, those of the American.' *Okonite* wire has been before us in this country, and of late has been pushed forward by a well-known firm, and, I believe, its use has been extended; for all this portion of the business and its increase the American factory turns out the wire, and the present and future profits are credited to the American factory, not only now, but in the future. The *okonite* wire will soon, according to the prospectus, be manufactured here, and the business is expected to be large; the English profits are therefore increased by the home consumption of home-manufactured wire, instead of obtaining it from the States; but no alteration has been made in the prospective profits, on account of the American branch losing all the British, and, probably, European trade. In fact, the American branch is calculated to yield an increasing profit on business now shipped here, which will, according to their own showing, be taken away from them by the English factory.

"It may not be valueless to point out that the com-

pany is formed to acquire the business of the *Okonite* Company, and to extend this special insulation. The patents in connection with this wire are for various modes of manufacture, and the material called '*okonite*' is a compound in which rubber plays the most important part; the combination is a secret, and is therefore valueless from a monetary point of view."

## OVERHEAD TELEGRAPH WIRES.

THE small majority of three, by which the London Overhead Wires Bill was recently rejected, seems to show that opinions on the subject are pretty equally divided, and that it was a mere chance that turned the balance against the measure. The Bill conferred upon officials of the London County Council powers of compulsorily entering upon private property at any time for the purpose of putting up wires and inspecting them; and, with the usual exaggeration, many of the speakers drew pictures of the terrible and outrageous infringements of private rights which would ensue if freedom of access were given to workmen to the roofs of houses to place new poles or repair wires. One member stated that since he had given a telephone company permission to put a wire over his house, it "had never been his own. The inspectors were always in and out, his stair carpets were worn, and his silver had to be constantly locked up for fear it should be stolen. The poles, moreover, were fixed so badly, that considerable damage was done to the roof of his house. The company declined to repair the damage, and it cost him £50 to put the roof in order when he applied for the removal of the poles. To that inconvenience every person would be subjected who had wires fixed to his house, and he protested against its being done whether an owner or occupier objected to it or not. The question was not one of erecting telephone wires, but of electric lighting wires, with the erection of which they were threatened all over London, and which was a very much more serious matter. They were in the infancy of the system, and yet they had already realised that those wires greatly increased the risk of fire, a proof of which was that the insurance offices had raised the rates for that property to which electric lighting wires were fixed."

We cannot but believe that the hon. member's statement is an exceedingly highly coloured one, though it may have some foundation in fact; but even granting that it is correct in the main, there ought to be no difficulty whatever in so amending the Bill that such inconveniences as those described should be reduced to a minimum. It was also stated that workmen claim the right of access at all hours to a roof where a telephone pole is fixed; and, further, that the Bill would empower the Council's officers by day or night to enter into private houses. With reference to this, it was pointed out that one of the great dangers of the overhead wires was that there were in London a great number of derelict wires, and therefore it was most necessary that workmen should be appointed by

the local authorities to deal with the wires. Clause 8 of the Bill provided that the inspector of the Council might enter a private house provided he were in uniform, and duly authorised in writing by the local authority, and provided that notice had been previously given. The inspector might then enter at some reasonable time to be named by the occupier. The rights of householders are thus most stringently guarded.

The great objection to the Bill was that power was given to put up a pole against the will of the owner of a house; but, as Mr. Courtney pointed out, the clause empowering this to be done could be struck out, but it was entirely a different thing to oppose a Bill which was admittedly a useful measure; this reasonable argument, however, did not appear to have much weight, and, for the present, things are to remain as they are.

#### Primary Batteries.

SOME of our contemporaries have commented upon M. Weymersch's primary battery without apparently perusing the report upon which their remarks are ostensibly based. One compares the cost of producing electricity from galvanic elements with that of central stations, and the result is naturally against the battery; furthermore, for the manipulation of the apparatus, it is contended that a new form of domestic servant must be forthcoming, although in reality the duties attached to filling and emptying the cells are but little more onerous than those entailed in a bath room. To say that the everyday attention required for a battery of this type is quite beyond the resources of small houses is altogether erroneous, and simply shows that the writer is not acquainted with the means adopted to reduce the labour and time employed on the battery to a minimum. In another important exchange it is stated that "though only intended for use where steam power is not available, the Weymersch battery gives results almost comparable with steam engine and dynamo." How this conclusion was formed we know not; certainly the report does not lead to such a belief; but perhaps the plant with which our contemporary is best acquainted is expensive to maintain. At all events the report seems to have been passed through a "Hedgehog transformer;" in no other manner can we account for the impression which was produced in the writer's mind.

#### The Rival Systems.

THE comparison of the battery *v.* the steam engine and dynamo, brings up another question, one which we discussed at considerable length in our leading columns for June 20th. From figures which have been sent to us, it appears that an average of 17 to 18 lbs. of good coal is used in alternating current stations per net unit sold; whereas the amount necessary in supplying the continuous current on the three wire system, with or without accumulators, is just about half, viz., from 8 to 9 lbs. Furthermore, we are assured that the total cost of engine room expenses, which includes fuel, water, petty stores and wages, was, in the case of a West End company, averaged throughout last year, a trifle under twopence per unit for the continuous current supply. The figures for another station, working alternating machines and transformers, averaged for the best three months of the year, showed the cost per unit to be

over sevenpence; and in another instance, that of a provincial station, over ninepence. Summing up, the data placed in our hands leads to the conclusion that at the present moment the companies working continuous currents, with or without accumulators, are producing electrical energy in the engine room at less than twopence per unit, whereas in the case of alternating current stations, the average appears to be over sevenpence. It seems almost impossible that there can be such a difference between the cost of production in the respective systems, but our informant stands so high in the profession and has had such great experience in central station working, that we hesitate to think he has made a mistake; the matter, however, is one demanding serious consideration, and we shall be glad to learn that the cost given for alternating working is open to modification, for unless we know all the circumstances and conditions of supply, the steam engines employed, the kind of drive, and, above all, whether the station considered as a whole, or the factors of which it is composed are working up to their full capacity or only partially loaded, the figures can scarcely be accepted *in toto* as fairly representing the merits of the two systems. Perhaps the London Electric Supply Corporation will favour us with an analysis of its working expenses!

#### The French Submarine Cables.

THE Direction General of the French Posts and Telegraphs is much occupied at the present moment with the establishment and repair of telegraph cables. In concert with the Post Office, the Administration is considering the laying of a new cable between London and Paris. M. Selves has also submitted for the approval of the Minister of Commerce a report on the defective condition of telegraphic communication between Tunis and Algeria. The attention of the Director-General has been called to this state of affairs by the Governor of Algeria and the French Resident General in Tunis. In reality, the State only possesses three Franco-Algerian cables. One of these was laid in 1871 and works in very bad condition, the other not being much better. The third alone works well, but is not sufficient to ensure the service. The sole solution consists in the laying of two new cables uniting Marseilles to Tunis and Oran. It is in this sense that M. Selves has drawn up his report and asks the Minister to get the Chambers to vote the credits necessary for the immediate laying of these cables. M. Selves has also asked M. Jules Roche to obtain other credits with a view to improving telegraphic communications with Corsica, the defectiveness of which was so much remarked upon during the tour of the President of the Republic.

#### Smoke Abatement.

THE "smoke annihilator" invented by Mr. Samuel Elliott, of Newbury, and to which we called attention in our last issue, may do all that is claimed for it, but no data is to hand as to the cost of and power demanded in working the apparatus, or its reliability; neither have we seen a report upon it by anybody claiming to be an authority in mechanical engineering matters. It is an easy thing to get together a heterogeneous assemblage of individuals who, without being at all acquainted with the process they are invited to view or of its mechanical details, are always ready to pronounce the apparatus capable of effecting a revolution in any industry to which the

inventor intends it to be applied. Until some details of its performance outside the inventor's premises are available it would be unwise to express any definite opinion on the subject; at the same time we hope that Mr. Elliott's sanguine anticipations will be realised.

#### The Electric Lighting Acts.

A WELL-KNOWN electrical corporation has registered several local companies with nominal capital for the purpose of obtaining provisional orders under the Electric Lighting Acts. Lest any misapprehension should exist as to the policy of this move, we may mention that it is rendered necessary by the attitude which has been taken up by the Board of Trade in practically declining to allow a provisional order to be assigned. In the places where the corporation has applied for provisional orders it has definite and valuable interests to protect, and if it had not so applied in these places it would incur the risk of losing its rights there. It must be obvious that it is not practicable for a manufacturing and contracting company to permanently work provisional orders in a large number of provincial towns, and as the Act also provides that the undertakers shall in the case of each provisional order keep separate accounts of the undertaking, it is advisable for these reasons alone to register in each place, where there are interests to protect, a local company with a nominal capital, to be increased as circumstances require.

#### Experts' Opinions.

IT is admitted that the Blackpool Electric Tramway has been a commercial success, but this has been attributed by experts in some quarters to the fact that the town is a summer pleasure resort, and that therefore the same happy financial state would obtain with horsed cars. Probably the majority of tramway men consider that the best paying lines are those having a regular traffic, so it is easy to show that the opinions to which we refer are mistaken ones. At Blackpool during winter not more than four cars are run, the mileage being only 45 per car day, whereas in summer eight to ten cars are employed, each with a daily run of 52 miles. To meet these conditions with horses would necessitate buying them when dear and disposing of the bulk of them when cheap, or keeping them in idleness and eating their heads off during the cold weather. How great the actual difference really is can best be shown by an incident which occurred during the summer of 1877. A breakdown occurred in the insulation of the line and horses were hired from one of the large tramway companies in a Lancashire town. During the month when horses were employed, the average cost per week was £113, but during similar periods of time previous to the hitch and since, the electrical working cost has not exceeded £45. It may be urged that using one's own animals would cost less than when depending upon the hire system; still the enormous difference between the figures above quoted must conclusively refute the statement that Blackpool would be as commercially successful if worked by horses.

#### Accumulator Traction.

A WELL-KNOWN engineer points out that though accumulators have been in the hands of capable engineers, backed with almost unlimited capital, still no system of working tramcars by these storage cells exists that can

be shown to pay. To contract at a price is one thing; to make the business pay, except by disposing of it to someone else, is another. The Elieson Company, says our authority, found its 4½d. per car mile contract cost nearly three times that sum, and the Brussels company, after a lengthened period of apparently successful running abandoned the method, because, as the chairman was reported to have said, "the system failed commercially on every point." Can any user of storage batteries show a set of cells which have been in daily use for tramcar work for 12 months and that are still in good condition?

#### The Cost of Electric Haulage.

WHILE upon the question of the cost of various electrical tramways, would it not be well if some systematic and generally accepted scale could be determined upon so as to show definitely what items should or should not be included under cost of haulage. There are not so many conflicting interests in this country at the present moment but that this problem could be readily solved.

#### Business Men Interviewed.

A REPRESENTATIVE of the *City Leader* has interviewed Mr. Joseph Smith, the managing director of the Electric Construction Corporation. The interview lasted but 10 minutes, but in that brief period a number of stupid questions were answered in such a manner that it is no wonder electric traction hangs fire in this country. What a lucky thing for the readers of the *City Leader* that Mr. Joseph Smith limits his conversational powers to just the sixth part of an hour.

#### The Tramways Institute.

THE Tramways Institute of Great Britain and Ireland held its annual meeting on Wednesday, at the Westminster Palace Hotel. The proceedings were remarkably dull until the reading of two papers on electric traction, when a lively discussion took place regarding the Barking line. We hope to deal with this subject in our next issue, especially as one gentleman advanced figures to show that the line was a failure from a commercial point of view. Yesterday (Thursday) some of the members visited the Barking Electric Tramway.

#### Seeing by Electricity.

WE are pleased to notice that the *Standard*, in describing the Celebration Jubilee of the Penny Post, alludes to the labours of the late Robert Sabine in the direction of "seeing by electricity." His experiments with selenium are probably now known to but few, and it is not difficult to identify the *Standard's* representative.

#### Burnand's New Burlesque.

MR. F. C. BURNAND has written to the *Times*. He has a grievance against the K. and K.E.L. Company, because its employes dig up the streets and pathways for the purpose of laying mains. We consider that the gentleman has little cause for complaint, and the company might give him a *quid pro quo* for allowing such feeble matter as sometimes disfigures the pages of *Punch* to appear under the guise of wit and humour.

FRENCH NOTIONS ON ACCUMULATOR  
TRACTION.

PERSONS who are either directly or indirectly interested in the development of electric traction, especially on the accumulator system, which appears to be, as yet, the best system applicable for urban and suburban traffic, are always seeking for data regarding, not only the initial cost of installation, but also as concerns the cost of renewing the plates of the accumulators, the amount of money for the depreciation of the motors, gearing, &c., the actual working expenses at the charging station, and the depreciation of the plant therein installed. No trustworthy details, with the exception of the first item, can be obtained in this country concerning these expenses, and time alone will bring forth the results. Everything, at present, is based upon estimates which are of no earthly use; absolute facts only are required. In this connection it is interesting to note that the estimate mania has arisen in France.

In the course of a few weeks there will be published in Paris a work which has been prepared by M. Paul Gadot, of accumulator fame. This gentleman's book establishes, or pretends to establish, a parallel between animal traction and electric traction by means of accumulators on tramways. The question in the two cases is the working of a tramway similar to those in Paris, the cars, cost of working, traffic, &c., being taken into consideration. The author presents three projects to solve the problem of electric accumulator traction. The first refers to that in which the accumulators are carried in the car itself; the second where batteries are independent of the car and are carried in a special car or waggon; and the third to cells arranged in a special waggon which also carries the driver, this being termed the electric locomotive.

M. Gadot extols the second system, which, according to his opinions, ensures the independence of the cars and accumulators, diminishes the working expenses, since the batteries are no longer put into place, or removed by hand one after another, in order to be recharged; and the cars do not have to be taken back to the dépôt to receive a set of freshly charged cells as they stop at the terminus where special cars containing newly charged cells are kept in reserve.

The *Bulletin International de l'Electricité* thinks that such a system would be objectionable, owing to the increased length of the car, and to the consequent interruption in traffic. Our contemporary might have added that such a system would necessarily augment the dead weight to be hauled.

From a financial point of view M. Gadot considers all possible combinations, and concludes in favour of electric traction, as follows: "We will suppose that the traffic is carried on by cars of the General Omnibus Company's type, each carrying 50 passengers and weighing 3 tons 7 cwt. when empty, and 3 tons 13 cwt. being the weight of batteries, motors, gearing, &c., making a total of 7 tons. Each car would travel daily 62 miles, and the average power developed is about 23 lbs. per ton. (?) The number of cars should meet the requirements of the omnibus company.

"In the first system suggested, by changing the cells three times a day, they are not quite exhausted, and the cost per car-kilometre comes out at  $4\frac{1}{2}$ d., or  $7\frac{1}{2}$ d. per car mile. In the second system the special car containing the batteries is changed three times daily, and the cost per car-kilometre is also  $4\frac{1}{2}$ d., or  $7\frac{1}{2}$ d. per car mile. In the third system the cost per car-kilometre is higher than in the two previous cases. Turning to the cost incurred by the Compagnie Générale des Omnibus de Paris for horse traction per car-kilometre, M. Gadot states that it amounts to  $5\frac{1}{2}$ d., or 9d. per car mile. This, then, is more than one penny per car mile in excess of the estimated cost of electric traction. Now, contends the author, from the fact of the reduction in the *personnel* of the company by the adoption of electric traction, by the letting out on hire or the sale of the

premises which would not be required, such as stables, granaries, &c., the Compagnie Générale des Omnibus would be able to reduce its capital by nearly £310,000!"

M. Gadot appears to neglect the most simple system of carrying the accumulators under the car seats, and the motor and gearing under the body of the car, for the complicated and certainly more expensive system, both as regards initial expenditure and maintenance, of employing a second car to carry the accumulators. This has been so demonstrated by the Stratford *fiasco*, although the system there employed was slightly different to the author's favourite, but it corresponded to the third method suggested by M. Gadot. Then, again, the cost of maintenance and depreciation of plant appear to be left out of the question. Taking the estimated cost of renewals alone at from 1d. to  $1\frac{1}{2}$ d. per car mile, or a mean of  $1\frac{1}{4}$ d., the cost of accumulator traction in Paris would exceed that now incurred for horse haulage, and the estimated reduction of the capital of the Compagnie Générale des Omnibus by nearly £310,000 entirely vanishes, although a saving in stabling, &c., would be effected. M. Gadot also leaves out of consideration the drivers' wages, &c., both as regards horse and electric traction. If he could furnish reliable data concerning the four accumulator cars which have been running for some time on the Madeleine-Levallois line of the Compagnie des Tramways du Nord, in Paris, M. Gadot would render great service to the electrical profession, who do not require, and will not accept, bare estimates on electric traction. In the meantime, we do not see the utility of a treatise containing estimates and devoid of facts.

THE GAS COMPANY AND THE ELECTRIC  
LIGHT AT BUDAPEST.

[FROM A CORRESPONDENT.]

THE question of the electric light at Budapest seems on the point of developing into a genuine sea-serpent, and if, after my repeated reports on the different phases of this affair, I refer to it again, it is merely because I consider it instructive for the widest circles, and consequently also for your readers, in so far as many municipalities which are in the same position as Budapest as far as lighting is concerned may learn from the proceedings there what a city ought *not* to do if it wishes to defend its own interests.

In my former reports I have already explained in what a peculiar position the city of Budapest is with regard to the existing gas agreement, as the gas company, up to 1891 inclusive, has the exclusive right of utilising municipal territory (streets, lanes and squares) for any lighting purposes whatever. Now, instead of looking out betimes that the city after the expiry of this monopoly should at once enter into the actual enjoyment of the recovery of its freedom of action, the city has for some years allowed itself to be led astray by the gas company, which, according to circumstances, boasting partly of alleged agreement rights and partly professing a benevolent readiness on its part, has with refined craft hitherto succeeded in keeping back the city from a definite decision on the lighting question, and in this manner to postpone the grant of a concession for the erection of electric works at Budapest. After the gas company first emphasised its—merely alleged—right by agreement, according to which negotiations with other lighting companies could be undertaken only after negotiations with the gas company, and after it had attained its purpose of protracting such negotiations as long as possible, it declares itself willing to take the electric lighting in hand (naturally!) and to enter into negotiations to that end with the municipality. As a matter of course, during these discussions the negotiations already entered into with other parties were broken off, and the gas company could again say to itself, "Time won, every-

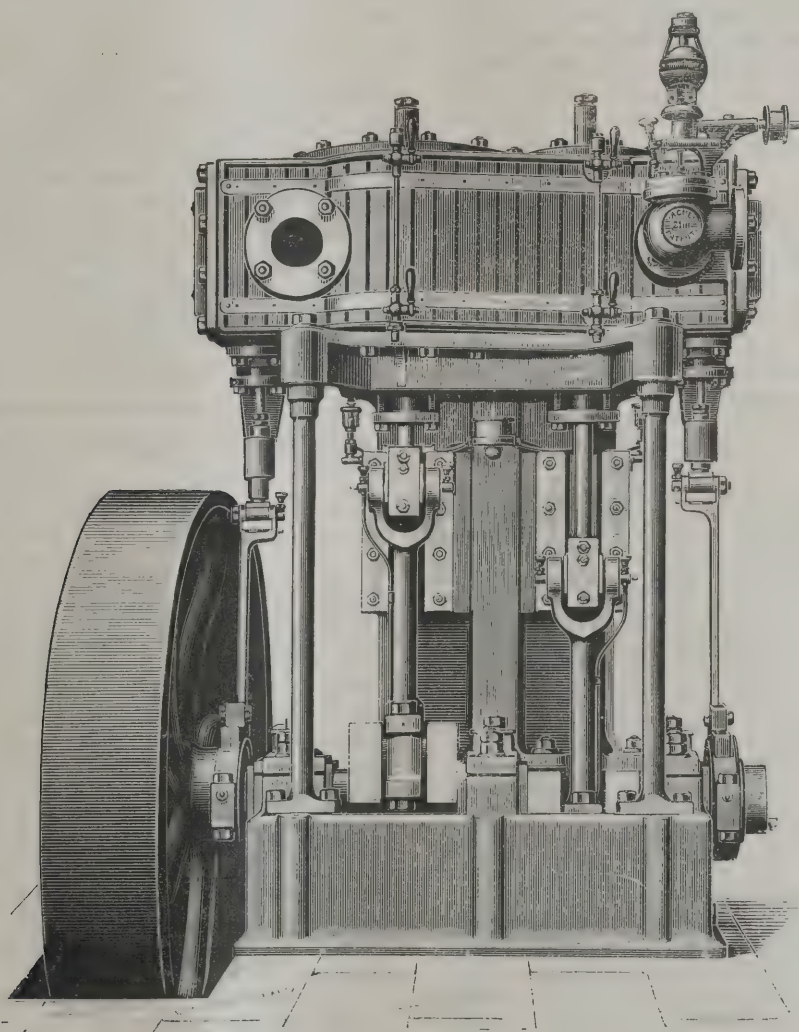

thing won." When, then, the gas company, after a considerable time, thought it prudent again to move in the matter; it declared that it would magnanimously give up its monopoly (which has only two years to run) and make a few other concessions if the city would prolong their gas agreement for 15 years more. At the same time the gas company demanded that the question of electric lighting should be decided in the way of a *public competition*. The invitation to this competition, of course, could only be given after the formal conclusion of the negotiations with the gas company, which, it was to be foreseen, would be very tedious, and the company well knew how long electrical works have to be waited for if they are to come into execution as the results of such a competition.

The City of Budapest in the meantime, which fancied itself at last at the goal of its wishes, accepted in principle the proposals of the gas company, and merely demanded the acceptance of a few further conditions which have been already communicated in your paper.

in preventing for an indefinite time the erection of electrical works at Budapest, and, without doubt, it has reached this object by an expenditure of cleverness which must be admitted. Whether this skilful management has been really prudent is another question. We see that many other gas companies, *e.g.*, the Società Anglo-Romana at Rome, and the Innsbruck Gas Works have secured and promoted their interests in an effective manner by erecting electric works, and uniting the two kinds of illumination in their own hands.

#### THE "CENTRAL STATION" VERTICAL SIDE-BY-SIDE COMPOUND HIGH-SPEED ENGINES.

THE annexed wood-cut represents a type of vertical compound engine, made by Messrs. Browett, Lindley and Co., which has become deservedly popular for

A few days ago the reply of the gas company was received, which in the most important points is in the negative! Now the negotiations may begin again, for the city thought that it merely needed to ratify the application for a concession which had been made years ago from another quarter, and had been already discussed by the municipal commission of lighting, and accepted in principle, in order in a short time to come into the possession of electrical works.

Meantime the Mayor of Budapest set off to Paris in order to study there electric lighting, with a view to utilising at home any observations which he might make. This is simply carrying coals to Newcastle, if we remember that the most important towns and lighting installations of the Continent have repeatedly sent representatives to Budapest, in order to study electric lighting there.

The gas company has, therefore, once more succeeded

electric lighting on account of the small floor space occupied for any given power, as well as for the simplicity of its construction, the steadiness of its working, and the high speed at which it can be run, thus dispensing with countershaft and large flywheel. In addition to these advantages all parts are easily accessible and removable for necessary examination and repair when worn.

The crank shafts are of mild steel, forged in one piece, most accurately finished in all parts, and well supported in three main bearings, of large proportions. The cylinders are cast of hard, close grained iron, and securely bolted to the vertical frame. The pistons are constructed on the most approved method, and fitted with broad cast iron rings, expanded by steel spiral coils.

One of the most important improvements in detail is the construction of the piston rod and cross-head, which

are forged in one piece of steel. This consists in cutting out the cross-head, so as to receive the brasses from the front, instead of from the bottom, and tying the jaws together by a solid steel cap, lipped over at each end, and bolted to the face of the cross-head by two turned steel bolts passing right through it, and serving also to secure thereto the broad cast iron slipper which rides on the slide face, the whole being screwed up tight, metal to metal, and the nut secured so as not to shake loose. The strain of working is thus not borne by the bolts, and these require no adjustment, the brasses in the cross-head eye being set up by separate screws actuating a broad wedge, and providing an ample metal to metal surface at this most important joint. The joint was invented by the makers, and has been used in all their electric light engines for years.

The well-known "Acme" patent governor is used on these engines, ensuring the greatest regularity under all variations of load, but automatic expansion can be provided when required, by using an improved drum governor on the shaft controlling the cut-off direct. For the higher pressures of steam, now in vogue (120lbs. and over), piston valves are provided on the high-pressure cylinders to reduce the wear and loss in friction.

### BELT STRENGTH.

By ROBERT GRIMSAW, PH.D.

THE problem often presents itself how to figure out in a moment whether or not a certain belt is strong enough to carry a certain horse-power at a certain speed. It is always well not to strain a belt, and sometimes there is not only danger of ruining the belt but a chance that breakage may work damage to business or property.

We will suppose that the belt is a leather one, running upon a cast-iron pulley. We know that the pull it exerts on the pulley is equal to the strain upon its tight "side," or fold, less that upon the slack side, or fold, and that this pull in pounds, multiplied by the belt speed in feet per minute, and divided by 33,000, will give the horse-power. (This is assumed as correct. It is true, and there is no time to prove it now.)

Of course leather varies in strength; and no matter how strong the belt is, if the lacings or other fastenings are weak, the belt will be in danger. The greatest strain upon the belt, in pounds, is equal to the breadth of the belt in inches, times the thickness of the belt in inches, and times the safe working strain per square inch of cross section of the belt; this latter depends upon the kind of leather and upon its fastenings.

As to these fastenings, it is safe to assume, as the result of experiments made, that for ordinary single leather lacings the average breaking strength is 950 pounds per square inch; single rawhide, 1,000; double leather, 1,200; double rawhide, 1,400; and riveted joints, 1,750.

Of course the safe working stress in pounds per square inch will be less than this; and we may put them about as follows: single leather lacing, 325 pounds; single rawhide, 350; double leather, 375; double rawhide, 400; and rivets, 575.

Working from this we find the square inches cross section of the belt to be for belts which are single leather laced 1-325, the greatest tension; where they are laced with single rawhide, 1-350; with double leather, 1-375; with double rawhide, 1-400; and where they have riveted joints, 1-575.

Thus, if we know that we are going to use a single leather-laced belt  $\frac{1}{4}$ th inch thick, and that it will have a force of 500 pounds on the pulley, and that the arc of contact will be 105 degrees, we know that the greatest strain on the belt will be  $500 \times 1.93 = 965$  pounds; and dividing this by 325 gives practically three square inches of cross section needed. As the belt is to be  $\frac{1}{4}$ th inch thick, it would need to be  $3 \div \frac{1}{4} = 12$  inches

wide. If it were  $\frac{1}{8}$  inch thick it would need to be only  $3 \div \frac{1}{8} = 12$  inches wide; and if  $\frac{1}{2}$  inch thick, only  $3 \div \frac{1}{2} = 9$  inches wide. For every arc of contact there is required a different multiplier; these are got from tables which have been calculated by correct theory and proved by accurate experiment. Thus, for 30 degrees arc of contact the amount of pull upon the pulley is 0.189 times the greatest strain on the belt; for 60 degrees it is 0.2967 times; and so on, according to the following table:—

Arc of Contact.	Multiplier.
30°	0.1890
45	.2695
60	.2967
75	.4082
90	.4673
105	.5181
120	.5650
135	.6098
150	.6494
165	.6803
180	.7143
195	.7409
210	.7692
240	.8130
270	.8475
300	.8772

This table (from the *Electrical World*, which is here published for the first time) is very convenient for ready reference when it is desired to know how much actual drive can be had out of a belt having a given breaking strength. Thus if we have a leather belt the safe-breaking strength of which is 1,000 pounds, we may know that all the pull that it can be made to put upon a cast-iron pulley, with 90° arc of contact, will be  $1,000 \times .4673 = 467.3$  pounds; but if the arc is 180° we will be able to get 714.3 pounds pull with the same maximum strain upon the belt.

### THE MANAGEMENT OF ACCUMULATORS.\*

By J. K. PUMPELLY.

#### IV.

IT was discovered by Planté, and by the experience of others since, that many more hours of discharging are needed to convert the positive plates into a peroxide of lead than to change the negative plate into finely divided lead, which is evidently the process necessary, as far as practical results go, to make the battery efficient to its full capacity. To do this, one or two charges and discharges are necessary, so that in reality we cannot expect to obtain our estimated percentage of efficiency until this forming work has been done, by the current of electricity put into the battery and taken out of it. Let us suppose now that this has been done three times consecutively, then we make our test trial. We have the 30 batteries and a series of 10 60-volt lamps connected, and we find that these 10 lamps are burning well up to candle power for seven hours; that is, 70 ampère hours have been consumed, and the voltage of the battery stands at 58 volts. Hence the lamps will burn two hours and a-half more, making 95 ampère hours of useful work, but not with as high candle power. Now we find it best to take off the lamps, leaving about 20 per cent of the charge still in the battery. This method is preferred, as it seems to prevent the action of the sulphuric acid directly on the lead plates, and also shortens the time of the next charge. Now we charge again with a current of 20 amperes, and find that after five hours' run in discharging on 20 lamps we have about the same efficiency as before. Again we increase the charging current to 20 amperes, and the discharge to 30 lamps, and find a slight loss in our heretofore fair percentage. Hence we conclude by experience that a 25-ampère charging current is sufficient for a 100-ampère hour battery, and the discharge is not economical over the rate of 20 amperes per hour. This rate of charge and discharge we will call normal. A larger rate of either we will

\* *Electrical World*.

consider maximum. We get quicker work, which is supposed to be needed, but not so economical as to efficient percentage. If it should happen that the charging current was not cut off at the end of five hours, the current that still flowed through the battery would be of no good nor do any harm. It would be like splashing water over the top of a tank after it has been pumped full.

In watching our next charging, we may find that one cell in the series does not act like the others. The surface of the electrolyte remains quiet, and no bubbles appear on the surface. We try the voltmeter on the circuit, and find that we are two volts short; instead of a fraction over 60 volts we have but 58. We must try every cell, using the double reading on our Weston voltmeter, which is divided into thirtieths and has a double-pole standard or connection fastening one wire to the small standard and one to the larger one. This will give us the reading on the lower line for two or four volts and thirtieths of a volt. Now we must find out, by testing each cell for voltage, where the loss is, testing along the line thus with two insulated wires, the ends of which are attached one to the north pole of the voltmeter and one to the south, and the other two ends cleared of the insulation and slightly sharpened. We touch the two poles of each cell, and find after several tests that one cell in the series shows a very low voltage; here must be the trouble, and after closer examination we find a contact between the plates in the battery which actually short-circuits it, and merely allows the current to pass through to the next cell, the same as if the two poles were fastened to a wire reaching across to the next cell. We must take this cell out, and as it is behind the others in the charge, must wait until they are all discharged. Then, after separating the plates, begin anew with the others. If we do not take this precaution, we shall find this cell unequally charged, and thus a drop in our E.M.F. before the battery has done its estimated work. However, when a battery is well formed and equally charged and discharged for a few days, this seldom happens until the batteries have been in use several months. But it does happen with nearly all the styles of batteries now made, and it is impossible to tell when it will take place, especially if the work the battery is forced to do demands at times a discharge in ampere current much over normal, that is 70 or 80 ampères, the tendency being to bend and twist the plates, and thus bring those of opposite poles together so that they touch. This uncertainty is what throws a shade of hazard over the calculations of those using such storage batteries, and is one of the strong objections to placing them in work demanding certainty of performance. Every effort is now being made to make batteries in such a way as to avoid this, but the writer is strongly of the opinion (and practice for one year bears him out in this) that it cannot be done unless the plates are prevented from touching each other, under any strain of work, by some fibrous absorbent that will not disintegrate in the acid nor increase the internal resistance. This the writer has accomplished, so that short-circuiting, that is buckling, cannot take place.

In order to gain this advantage the writer departs from the general mechanical method of building the batteries. Heretofore the plates in all batteries have been placed in an upright position in the cell, face to face and depending entirely upon their own atomic tenacity to hold together. Strips of hard rubber or small buttons of the same material are placed between the plates to prevent their touching each other. This method of separation often fails, especially when a heavy current tends to buckle the plates. There is also a constant tendency in the active material to flake off, or even to fall out and be held between the plates, thus short-circuiting the battery; also a danger from trees of lead, or specular crystals of lead, which form between the plates, and produce the same deleterious action, and which can not be prevented or guarded against. These crystals are very fine, almost needle-like and imperceptible. Another trouble shows itself when the plates are most active. The positive ones

become very porous and spongy, and then they fall apart and disintegrate, and the cell is ruined.

The method of building batteries, mentioned above as being an exception to the rule, is this: The plates are placed one over the other, horizontally in the cell, the positive all held together by strong lead lugs, which are cast on each plate. These lugs are hollow and tapered, and are pressed into each other firmly. The negatives are treated in the same manner. Through this continued lug a heavy copper wire is run, and molten lead poured down the lug and around the copper, thus making a firm contact, both chemically and mechanically. Then the two sets of electrodes are slid together, and a peculiar kind of cellulose fibre is placed in thin sheets between the electrodes. This fibre absorbs freely, is a non-conductor, and is of so small resistance to the passage of current or the gases formed in decomposing the water, that it cannot be detected, either in practice or by test. The fibre is of great durability in the acid, and is just close enough in its mesh to prevent any minute material from passing or washing through from one electrode to the other. Thus the plates being supported, and feeling no strains that might tend to disintegration, last much longer than other forms of battery, and when, in the course of two or three years, the positive plates may need renewing, the old ones can be drawn out, and an entire new set slid in.

It is found that the copper wire, imbedded in the lug, carries a larger amount freely, and a discharge of 80, 100 and 125 ampères does not disturb the plates.

---

#### STANDARD SPECIFICATIONS FOR ELECTRICAL PLANTS.

---

THE new catalogue issued by the United Edison Manufacturing Company of America, besides containing an excellent description of the Edison apparatus, embodies a form of standard specifications for electric light plants. These specifications, which we print below, are the result of a large experience in this class of work, and give a very good idea of the manner in which installing is carried out in the States.

*Dynamos.*—The dynamo must be of such type and must be so connected as to operate with the highest economy, either separately or in multiple arc (in case there be more than one dynamo), and so that in such case the load may be shifted from one machine to another up to the limit of its full load without in any way affecting the candle power of the lamps. The dynamo must be capable of being operated for 10 hours continuously under conditions of full rated load without injurious heating of any part of the dynamo and without sparking. The dynamo must be of such design that the increase in power required to operate it from least load to full load shall be proportional to the number of lamps in operation. The dynamos must have a commercial efficiency under full load of not less than 85 per cent. in dynamo, requiring three (3) horse power in belt, and of not less than 92 per cent. in dynamo, requiring one hundred (100) horse-power; and dynamos of intermediate size shall have an efficiency proportional to the efficiencies quoted. The commercial efficiency of the dynamo under conditions of one-quarter load shall not vary more than 8 per cent. from that at full load. Each dynamo must be provided with a belt-tightener, so that the tension of the belt may be altered at will while machine is in operation. The armature of the dynamo shall be perfectly balanced, so as to run at its rated speed without appreciable jar. There shall be at least two brushes on each side of the commutator. The insulation resistance between the armature and field coils and the base of the machine must be at least 200,000 ohms. Each dynamo must be placed on a solid wooden base, and must be thoroughly insulated electrically. (When operated continuously for 10 hours under conditions of full load, the temperature of no insulated wire or other

electrical portion of the dynamo shall rise in temperature more than 80° C. above the temperature of the surrounding air.) All dynamos shall be provided with self-oiling bearings, which, under normal conditions, shall not require attention, except when the dynamo is started.

*Instruments.*—Each dynamo must be provided with an ampèremeter in circuit with it, which shall show continuously the current said dynamo is producing. These ampèremeters must be constant, unaffected by any normal change in temperature, and unaffected in their readings by being placed at a distance of 6 feet or more from the dynamo. The ampèremeters must be accurate within 3 per cent.

A pressure indicator shall be furnished for each dynamo or set of dynamos operating in multiple arc. This pressure indicator must be connected so as to indicate directly and continuously the electrical pressure at the point to which it is connected. It must be constant in its readings, unaffected by normal changes of temperature, unaffected in its readings by magnetic influences at a distance of 10 feet from a dynamo, and must be so constructed that a variation of one volt will cause a deflection of the pointer upon the scale readily noticeable at a distance of 10 feet from the indicator.

A ground detector shall be provided which will indicate continuously the condition of each pole of the system as regards insulation to ground.

*Incandescent Lamps.*—Lamps furnished must be guaranteed to have an average life of six hundred (600) hours, and a corresponding economy of fifteen (15) lamps to the electrical horse-power. All lamps shall be of such uniformity when new that when operated at the voltage for which they are intended, both the power required and the candle-power of the lamp shall be within ten (10) per cent. of the rating. All lamps which give out from any fault within the first ten hours of the operation of the plant, shall be replaced by others without charge. All breakage of lamps beyond this, under normal operation of the plant, shall be considered under the guarantee as to average life. Lamps shall be furnished varying in candle-power from sixteen (16) to one hundred (100), there being at least three (3) different candle-powers between sixteen (16) and one hundred (100). Lamps of different candle-power shall require power in proportion to their candle-power.

*Pole Line.*—The pole line shall be composed of straight, select, shaved poles. All poles must be set perpendicularly, and must be thoroughly guyed, whenever necessary, to insure this result. They must be set one-sixth of their length below the surface of the ground. All poles must measure at least five inches in diameter at top, and where more than one cross-arm is required, they must measure not less than 6 inches in diameter. They must be housed and gained (*sic*). All cross-arms shall be thoroughly seasoned and free from knots, and painted. All cross-arms must be secured to poles in substantial manner, so that they shall be at right angles with line of pole and parallel with each other, and accurately fitted into gains. All poles where cut-outs are placed shall be stepped. The poles shall not, under any circumstances, be set further apart than one hundred and fifty (150) feet, and in heavy line work they shall not be set more than one hundred (100) feet apart.

*Overhead Conductors.*—The overhead conductors shall be of bare copper in systems using less than five hundred (500) volts. The pressure lines and service lines shall be insulated by weatherproof insulation. Whenever the conductors are likely to make contact with other materials than the insulators or poles (except leaves) the conductors shall be properly insulated therefrom. No overhead wire having a span of over ten feet shall be run in closer proximity to any other wire than ten (10) inches. All joints shall be made in substantial manner, so that no movement of the two ends relative to each other is possible, and so that the joint is as strong as the wire itself and makes thorough contact. All joints must be soldered. All overhead conductors exposed to influence of atmospheric electricity shall be protected therefrom by suitable lightning arresters.

In all cases where other wires are run above the conductors under consideration, a guard wire must be run to protect the latter from contact with the former.

*Wiring and Wiring Devices.*—For convenience in reference the wiring will be treated under two heads, the supply wires and the distributing wires.

No distributing circuit shall carry more than five (5) ampères. The distributing circuit shall lead from the distributing cut-outs, which shall be grouped together in cut-out cabinets at various distributing points in the building. Any doors, locks, hinges, &c., if desired for these distributing cut-outs, shall not be furnished by this contractor, but the cut-out cabinet shall be prepared ready for them by the contractor. The maximum loss in any distributing circuit not to exceed two (2) per cent. The cut-outs at each distributing point to be supplied by mains, which mains shall be so proportioned that under any conditions of normal load there shall not be a variation of pressure throughout the mains to exceed two (2) per cent. The connection to the distributing cut-outs from the mains shall be made through double pole fusible cut-outs of proper dimensions. In case current be supplied to the mains through feeders, there shall be fusible cut-outs placed at the points where the feeders join the mains, such cut-outs being placed both at the terminal of the feeder and upon the main immediately on both sides of the feeding point. All lines leaving the dynamo room shall be protected by fusible cut-outs, and in addition thereto any wire leaving dynamo room and carrying a current of more than five (5) ampères shall have a switch in circuit with it. In all moulded or concealed wiring where insulation of the wire makes contact with material other than special insulating material designed for the purpose, a wire of following makes, or equally as good grade and acceptable to the purchaser, shall be used: Edison Machine Works, Grade 3, Habirshaw, Okonite, Grimshaw, Kerite, Clark Safety Insulator. In the case of cleated work, where the wire will never, under normal conditions, be exposed to any moisture, an insulation of the quality known as weather-proof can be used, such as the following or their equivalent: Edison Machine Works, Grade 1, P. & B., K. K., Roeblings's Weather-proof, Ansonia Brass and Copper Co.'s Weather-proof. In all work in connection with the wiring, the wire must invariably be handled so that if the wire were bare the insulation would be the highest possible under the conditions. In other words, the insulation must not be relied upon any more than is absolutely necessary. No wire smaller than No. 18, Birmingham Wire Gauge, or No. 16, Brown and Sharp's Gauge, shall be used. In all cases the ampère capacity of the conducting wires must be carefully determined, and the size of the wires so proportioned that the maximum current carried by them under normal conditions shall not occasion a rise in temperature exceeding sixty (60) degrees Fahrenheit. The wiring must be done in such a manner that in case a different system be used from that originally contemplated, there will be the least possible expense involved in changing the wiring to adapt it to any other system. All joints must be made in substantial manner, so that no movement of the two ends relative to each other is possible, and so that the cross-section of contact is at least twice the cross-section of the conductor. All joints, except when surfaces are held in contact by strong pressure, such as by screws, shall be well soldered and well taped. In all cases where the wire is concealed from view the joints shall be thoroughly covered with some first-class waterproof compound before being taped. All wires that pass through floors or that rest against any metal work shall be protected by a tubing of hard rubber extending at least one inch in each direction beyond such floor or metal work. With all safety devices open, the insulation of any single section of the wiring shall not be less than 100,000 ohms. The combined insulation resistance, when all sections are connected up for service, shall be the highest obtainable when each section measures 100,000 ohms. Metallic staples for fastening wires shall not be used unless there be placed between the insulation of the wire and the

staple some insulating and non-combustible material. Electric light fixtures or gas fixtures carrying electric light wires, if attached to gas pipes, must be insulated therefrom by insulating joint or other suitable means, so that there shall be a high electrical resistance between such electrical light wiring, such fixtures and the system of gas pipes. The wiring must be so proportioned that the maximum variation of electrical pressure at the lamps in different parts of the building under any normal conditions shall not exceed two (2) per cent. All wiring must be neat in its mechanical appearance and arrangement. All points in regard to wiring not above specified shall conform strictly to the requirements of the National Board of Fire Underwriters. All cut-outs shall be made of insulating and non-combustible material, such as porcelain, glass, &c., and shall be double-poled. All switches shall be mounted upon insulating and non-combustible bases, and if covered, shall be so designed that the switch is merely set by hand ready for the break in contact, and the actual breaking of contact shall be done automatically and beyond hand control. The act of making and breaking contact in all switches shall cause the surfaces in contact to be subjected to sliding friction in order to keep such surfaces of contact clean. All sockets shall be of same dimensions relative to the base of the lamp, so that any standard Edison lamp of any candle-power will fit any socket. The socket shall be of substantial, workman-like construction, and all portions of the shell and key shall be thoroughly insulated.

### DIRECTORS' LIABILITY.

LEST our readers should imagine that we have inspired Public Bill No. 300,\* at this present moment worrying itself through its stages in the Imperial Parliament, we hasten to disclaim the honour. "A Bill (as amended by the Standing Committee on Trade) to amend the law relating to the liability of directors and others, for statements in prospectuses and other documents soliciting applications for shares or debentures," is prepared and brought in by Mr. Warmington, Mr. David Thomas and Mr. Neville, who deserve the thanks of all investors for raising the question. Its advent is not too early in the day of joint stock association, and no one can accuse it of not being sufficiently drastic or unnecessarily long. It contains four clauses:—The first, the title; the second, intimating that it is to be construed with the other Companies Acts; and the fourth, as amended, that it shall come into operation on the first day of October, 1890. Until that date directors have a close time, and may be expected to evolve prolifically. One clause only, clause 3, forms the body of the Bill; but this one is sufficient to make directors *in posse* "sit up."

Where a prospectus or notice invites persons to subscribe for shares in or debentures or debenture stock of a company, every person who is a director of the company at the time of the issue of the prospectus or notice, and every person who is named in the prospectus or notice as a director of the company or as having agreed to become a director of the company either immediately or after an interval of time, and every person who has authorised or is responsible for the issue of the prospectus or notice, shall be liable to pay compensation to all persons who shall subscribe for any shares, debentures, or debenture stock for the loss or damage they may have sustained by reason of any inaccurate or misleading statement in the prospectus or notice, or in any report or memorandum incorporated therewith or referred to therein, unless he proves—

(a.) With respect to every such inaccurate or misleading statement of fact not purporting to be made on the authority of an expert, that he made reasonable inquiry and examination into the statement and had reasonable ground to believe, and did then and up to the time of the allotment of the shares, debentures, or debenture stock, as the case may be, believe that the statement was true; and

(b.) With respect to every statement or extract purporting to be a statement of, or an extract from, any report or valuation of any engineer, valuer, accountant, or other expert, that it was a true and fair statement of, or extract from the report or valuation, and that the report or valuation was made by the person whose name

\* This Bill has passed for third reading.

it bears, and that he had reasonable ground for believing, and did then and up to the time of the allotment of the shares, debentures, or debenture stock, as the case may be, believe, that the report or valuation was made in good faith, and that the person making it was competent to make it; or unless he proves that he had not consented to be become a director of the company, or that having so consented, he withdrew his consent before the issue of the prospectus or notice, and that the prospectus or notice was issued without his authority or consent.

It is possible that the gentlemen who back the Bill are not intending to set up in the directorial line, for that line, if the Bill were to become an Act as it stands, would not fall in pleasant places. However wisely we may have loved the director, it has not been our lot to love him too well; but in his hour of trial we beg to extend him our sympathy. We read in the daily press that Mr. Warmington has been warmly congratulated on his Bill. Possibly, but by whom? Not by directors surely, nor by anybody who has seriously considered the question with a full knowledge of the subject. We are inclined to agree with Sir Roper Lethbridge who, in moving an amendment, remarked that the whole Bill is in a chaotic condition. Supposing it to have become law as drafted, no sensible man would be a director, nor would any respectable office boy's mamma allow her son, on leaving the Board school, to serve the Board room, for "others," defined as "every person who is responsible for the issue of the prospectus," would seem to include the secretary, solicitors, bankers, auditors, clerks, boy, porter, and possibly the printer and postman. We have heard of men who, sighing for some one willing to incur the expense of making them bankrupts, sighed in vain. To this class we should have to look for directors—to those who have nothing to lose; and the last state of the shareholders would be worse than the first. The most common sin of directors is ignorance of the business they have to direct; but this very ignorance is to some extent often a necessity and pleadable as an extenuating circumstance; relying on "experts," they have not all the knowledge to enable them to judge who is an expert and who is not. As amended, the word "expert" is to include any person whose official or professional knowledge gives authority to a statement made by him. Another amendment is, that a director is to be exempted from liability where he has reasonable grounds for believing a report or valuation was made by the person whose name it bore, after reasonable enquiry and examination.

It would not be well for companies that men of means should be afraid to accept seats on boards. There are plenty of company directors in both Houses, so let us hope a workable measure will be finally turned out at which all honest men may rejoice.

Promoters of traction companies please note.

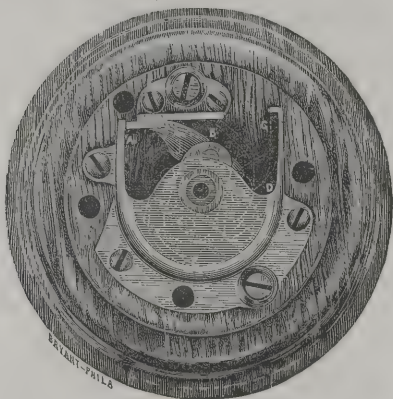

### THE PAISTE SWITCH.

WE illustrate in our columns to-day a novel switch designed and patented by Mr. H. T. Paiste, of Philadelphia, Penn., U.S.A. This switch has met with deserved success in America, where over 100,000 are in daily use, and judging from a number of letters which Mr. Paiste was good enough to show us, it has evidently been adopted by all the leading electric companies of that country.

Mr. A. Reyrolle, of London, has secured the European rights to manufacture and sell this switch, and has furnished us with the following description:—

It was the object of the inventor to abandon the use of spring metal for electrical contact, as practice had demonstrated that metal soon lost its elasticity when under the action of electric currents, and with this in view he used two plates (made from sheet brass), one U-shaped, the other being straight. These are shown in the accompanying cut, mounted on a base of non-conducting material. The binding screw on U-shaped plate is the terminal of one circuit wire, and the screw on straight plate the terminal of the other. Two arms,

A and D, are hinged to a spindle, the bearing of which is located in the centre of U-shaped plate. A spring joins the end of the two arms, which keeps the arm, A, pressing firmly against the straight plate, also the arm, D, against the U-shaped plate. As shown in the cut, the circuit is completed as the arm, A, joins the U-shaped plate and the straight plate, through its spindle and the arm, D, also at its point. To break circuit, the spindle is turned (by means of a handle screwed into its centre) to the right a quarter turn; by so doing the arm, A, slides along the straight plate (cleaning it) until the position, B, is reached (while the arm, A, slides along the straight plate it is lengthening the spring), at which point the straight plate becomes the tangent of a circle, of which the arm, A (hinged on the spindle), becomes the radius. As soon as the straight plate becomes the tangent, the arm, A, flies rapidly to position shown at C, when the circuit is broken. Whatever arcing there is is on back of arm and not on face where electrical contact is made. The

circuit is completed by a like movement, the arm, D, coming to rest in position shown by A. Each time the switch is used better contact is secured, as the arm seats itself in the straight plate, like a hammer blow. This switch, in various sizes, is now being mounted on china, with cover and handle of same material, making a small, neat and artistic fixture.

The Electric Supply Company, of Chicago, state that they have sold several thousands of Mr. Paiste's snap switch, and never had one returned nor a single complaint. A letter from the Sawyer-Man Electric Company, New York, says that they have sold thousands of the 10 ampère single-pole switch, no complaints having reached them from any quarter; one from the Central Thomson-Houston Company, Cincinnati, is as follows:—"Having used several thousands of your switches, it gives us pleasure to be able to give them our hearty endorsement, and you are at liberty to refer to us at any time." The New England Electric Supply Company, Bridgeport, writes:—"We take much pleasure in saying that in our opinion the Paiste switch is incomparable. Of the thousands that we have sold, not one has been damaged either by burning or owing to mechanical defect. The economy in using the switch is obvious, while certainty of its action is of the utmost value." Central Electric Company, Chicago, say:—"We have handled many thousands of the Paiste switch, and we know of no complaints; on the contrary, our customers speak of it in terms of praise." Mr. Paiste showed us dozens of other testimonials to a similar effect.

**Storms and Electric Wires.**—It has for some years been the practice at the Berlin Post Office for the *employés* to make a note of storms and magnetic disturbances, direction of storms, length, &c., and the result has demonstrated that underground wires, without being entirely free from the influence of magnetic storms, are much less liable to disturbance than overhead ones; and, on the other hand, that accidents from lightning are much less serious in those towns where the overhead system is in vogue.

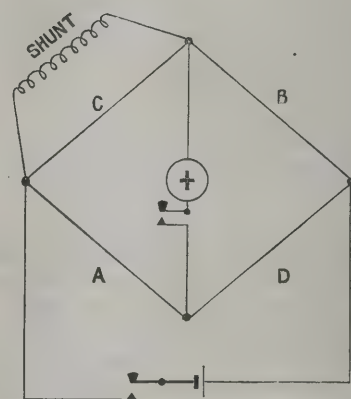

## ACCURATE MEASUREMENT OF LOW RESISTANCES.

EVERYONE who has had occasion to use the Wheatstone bridge, with the mirror galvanometer, for the purpose of measuring small resistances has suffered from the inconvenience and difficulty consequent on inexact balance, even when unequal arms are used.

Recently finding it necessary to obtain a very accurate adjustment with the bridge, with arms of equal resistance and not exceeding 100 ohms each, the minute differences of resistance existing between the arms, although nominally equal, rendered an accurate balance impossible.

The use of fine wires, sliding contacts and various other devices were tried, without any satisfactory result.

It then occurred to me to shunt one of the higher resistance arms with an adjustable resistance very much greater than itself, and this was found to be perfectly successful; alterations of the shunt, enabling a perfect balance to be obtained, although the conditions were such that a difference of  $\frac{1}{100000}$ th in the joint resistance of the shunted arm produced a deflection of one division.

This mode of attaining the condition of perfect balance has no doubt suggested itself to others, but does not appear to have been published before and it may be of service to draw attention to it now.

It is clear that it is not only useful in attaining a perfect balance with some predetermined fixed resistance, but may be employed in the exact determination of small fractions of an ohm which are now less accurately estimated by using arms of unequal resistance.

If determinations to  $\frac{1}{1000}$ ,  $\frac{1}{10000}$  or  $\frac{1}{100000}$  are required, the shunt should be respectively 1,000, 10,000, or 100,000 times the arm resistance, and it may be used to determine a resistance which by that amount is in excess of, or is less than, the resistance unplugged in the measuring arm.

For *plus* results in D the shunt should be placed across the arm A, and for *minus* results across the arm C; and it will be found in practice that this method admits of very exact measurements with great ease of manipulation.

A. EDEN.

## SHAPING FILAMENTS OF INCANDESCENT LAMPS.\*

WHEN the loop-shaped filaments of incandescent lamps are straightened by a weight during the period in which the air in the bulb is exhausted, the removal of the weight is found to be a rather delicate operation. In straightening the filaments in this manner it has

\* *Western Electrician.*

ordinarily been found necessary to attach to each lamp bulb an exhaust tube longer than usual. After the operation of exhausting has been completed, this tube is first sealed some distance from the globe, and the lamp removed from the pump. By manipulating the lamp the weight is unhooked from the loop and dropped into the tube, which is then sealed off from the lamp. The accompanying diagram illustrates an improved method of handling the weight by magnetism. A glance at figs. 1 and 2 will show the simplicity of the operation. The small weight shown

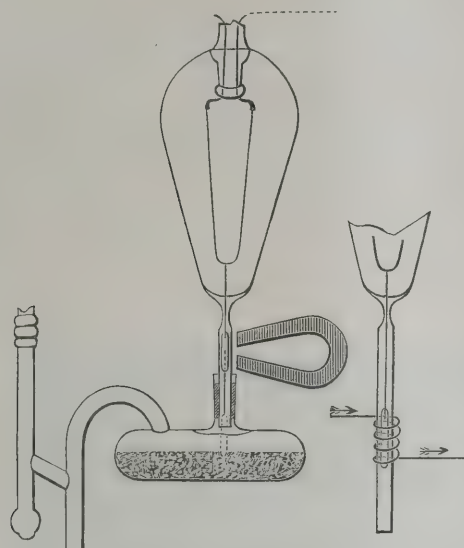

FIG. 1.

FIG. 2.

in the tube and hung on the filament is made of iron or other magnetic material. By this construction it is only necessary to use a magnet, as shown in fig. 1, or a solenoid, as indicated in fig. 2, and the weight may be manipulated as desired. It is evident, too, that the magnetism of the solenoid or permanent magnet may be employed to increase or diminish the strain or pull on the weight. This insures a delicacy of adjustment otherwise unattainable. This method of weight manipulation in the above-mentioned process is the invention of R. N. Dyer of New York.

### NEW MARINE SIGNALLING APPARATUS.

A NEW mechanical apparatus, in which electricity plays a part for night operations, has been invented by Mr. R. J. Crowley, for marine signalling purposes. The apparatus may be fixed to any top-mast, and consists of a hollow iron mast, from the right and left-hand sides of which project horizontally four oblong metal frames. Each of these contains two shutters, which in their normal position are horizontal, and which are mounted on axes so that they may be revolved. One side of each pair of shutters is painted vertically with red and white stripes, whilst the other side forms a white diamond on a dark ground. At the inner end of each shutter is fixed a recessed pulley over which passes a chain which on being pulled grips the pulley and causes the shutter to revolve. Only four working chains are required, the lower pulley of each frame being operated by a subsidiary chain suspended from its corresponding operating chain. The working chains are carried to the bottom of the iron mast, where they are joined to wire ropes extending to the deck of the vessel, or any other desired part thereof. The shutters represent the alphabet, and also certain signals. Thus on causing any shutter, or combination of shutters, to be exposed by pulling any one or more chains, any letter or words may be flashed. The four wire ropes are fastened to horizontal levers, so that by depressing or raising any one lever any message may be signalled. The operator has only in front of him the four levers and a card

upon which the code is printed. Signals may be transmitted with this apparatus with great rapidity, and by a mere tyro.

The electrical part of the apparatus comprises four electric lamps fixed at the four corners of the frames, and is only used for night signalling in conjunction with the same code. The four lamps are backed by coloured reflectors, and are connected with a battery or dynamo, as the case may be, through make and break switches. Thus on depressing any switch its corresponding lamp is placed in circuit and lighted, whilst on releasing the switch the light is extinguished. By this means any signal may be flashed. A fifth electric lamp is also fixed on the apparatus, and is used purely for lighting purposes. A company will shortly be formed to work this invention, which is of American origin. Further information will be furnished by Messrs. Salter, Hunt and Co., of 62, King William Street, E.C.

### SEEING BY ELECTRICITY.

THE exhibition, at the Jubilee of the Penny Post, held at the South Kensington Museum, of an apparatus called the electrophonoscope, though it no doubt answered the amusing purpose of a penny peep-show, did not advance, it is perhaps needless to say, the problem of seeing by electricity a single stage. The apparatus was, we believe, nothing more than a well-arranged combination of a telephone and the well-known optical delusion which enables the intelligent rustics at the country fairs to "see through a four-inch deal board," or through one of their companions equally hard craniums. In fact, as regards the "seeing" part of the apparatus, there was nothing electrical about it, except the illumination of the reflectors by incandescent lamps. It is now some years since the late Robert Sabine, Profs. Ayrton, Graham Bell, and others suggested that the problem of "seeing by electricity" might be partially solved by the aid of a series of selenium cells, arranged in a mosaic pattern, and upon which an image of the subject to be transmitted was projected; but no practical result seems to have developed from the crude idea. Edison, we hear, is working away at the question, but whether he has arrived at an approximation to a solution anything more definite than mere rumour does not indicate. An announcement that success had been attained would of course be heralded in the daily press by the usual stereotyped announcement of a "revolution in telegraphy, the far-reaching consequences of which it is impossible to estimate," words which, as regards the latter part of the statement are, no doubt, strictly true, as the almost invariable falsification of the prediction shows the inability of the "dailies" to estimate correctly the value of scientific discoveries. One great direct practical value of a really successful method of electrical vision would be great rapidity of telegraphic transmission, as—unlike the telegraph and the telephone, where the communication of intelligence is the result of a sequence of expressions one following after the other, and which, consequently, takes up time—seeing by electricity means the simultaneous transmission of the facsimile of all parts of a picture or object, which would be visible to an almost unlimited number of spectators; consequently, a long written or printed message, if made visible, could have its several paragraphs copied down each by a different person, and all writing at the same time.

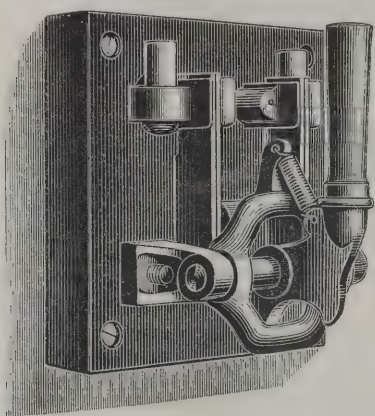

**The Post-Office Jubilee.**—The celebration reception and exhibition on Wednesday night, under the Presidency of the Duke of Edinburgh, seems to have been entirely successful. The feature which excited the greatest interest was the electrophonoscope show, a little delusion which reflected great credit upon its learned originators, and which caused many persons to go away under the impression that seeing by electricity has become an accomplished fact.

## NOTES.

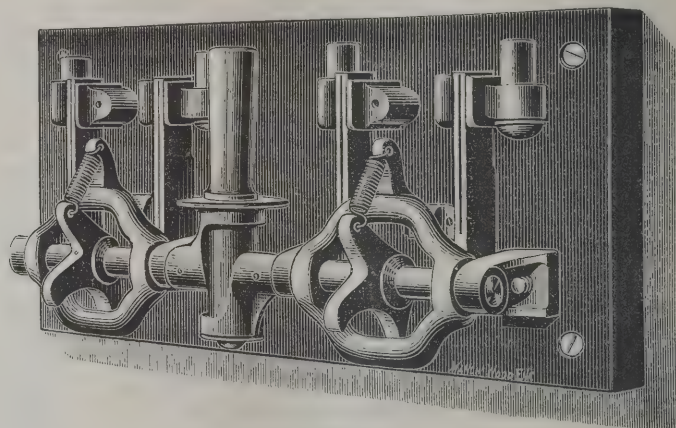

**Electrical Measuring Apparatus.**—In the report on the Weymersch battery, which we published last week, the names of Messrs. Sharp & Kent were inadvertently omitted from the list of those firms who so obligingly lent the testing instruments.

**Automatic Electrical Call Boxes.**—We understand that a similar call box to the one referred to in our issue of the 13th ult. has been patented in Germany, and that it is already in use in Breslau, Hamburg, and Berlin. It is very probable that one of this make will be shown in London in two or three months hence.

**Main Switches.**—Yet another series of switches, this time of the main or switchboard type, is about to be introduced by Messrs. Dorman and Smith, of Manchester and London. There is nothing strikingly novel about these switches, their principal characteristic being their extreme solidity. The illustrations show these arranged for use both for "single" and "double" pole. They are at present made in four sizes in both

SINGLE POLE SWITCH.

DOUBLE POLE SWITCH.

types, are of gun-metal, with steel shafts, and are mounted on slate slabs. They have a double break, good spring contacts, and instantaneous release, and being fitted with conical thimble terminals, arranged either on the front or back, are easy to couple up.

**Telephone Call Boxes.**—We are informed that in a few months telephone call boxes will be installed in various London districts, so that persons desiring to communicate with the exchange and then to subscribers may do so. The money to be paid for conversation will be deposited in slots, when the exchange may be rung up. Subscribers will, however, each be provided with a key which will fit into holes in the boxes, and by means of contacts inform the exchange attendant that the person desiring to communicate is a subscriber. Of course, the latter will not have to pay any fee other than his annual subscription.

**Death of the Swiss Director of Telegraphs.**—The death is announced of Herr Frey, Director of the Swiss International Telegraph Bureau, who was only recently appointed.

**Prize.**—The Société d'Encouragement pour l'Industrie Nationale has awarded to M. Gramme the Ampère medal.

**Messenger Call System.**—To advocate the claims of this system a conversation will take place at the Royal Institute of Painters in Water Colours on July 12th.

**An Error.**—Messrs. Crompton & Co. correct our statement made last week as to the price per unit at Chelmsford. It should be 1s., not 1s. 3d.

**The Tory Island Cable.**—The steamer *Buccaneer* left Silvertown on Wednesday to lay the cable connecting Lloyd's signal and telegraph station on Tory Island with the mainland.

**Corporation of Salford v. Lever.**—The judgment given against Mr. Lever at Leeds last month was upheld in the Queen's Bench Division on Saturday. It was intimated that there would be an appeal.

**Arc Light and Battery Carbons.**—A point brought out in the discussion upon Mr. Marks's paper on "Arc Light Carbons" at the recent meeting of the American Institute of Electrical Engineers, had reference to the control of the arc by means of a small energised coil in suitable proximity to it. According to Mr. Marks, it is possible in this way to maintain a perfectly steady, noiseless arc, and Prof. Thomson's experience supported this view. An American contemporary, however, thinks it doubtful, if the method possesses the requisite simplicity for commercial purposes. Our contemporary thinks also that the suggestion made by Mr. Pope at the same meeting, that some competent student should take up the study of battery carbons, should be acted upon, as it would result in the discovery of many valuable principles, and in the confirmation of many of the now accepted theories in connection with the battery carbon.

**Technical Education.**—At the Department of Science and Art of the Committee of Council on Education, South Kensington, a letter from Mr. J. W. Pye-Smith, Town Clerk of Sheffield, dated 16th May, 1890, was read, stating that the Town Council of that borough propose to make grants, under the powers conferred upon them by the Technical Instruction Act, 1889, to certain institutions in Sheffield for the promotion of technical instruction; that at one of these institutions instruction is given in the following subjects, which are not included in the branches of science and art, with respect to which grants are at present made by the Department of Science and Art, viz.:—1. Manual training or instruction in the use of tools for working in wood and iron; 2. Plumbers' work; 3. Electrometallurgy; 4. French; 5. German; 6. Type-writing; 7. Shorthand; and that, in the opinion of the Town Council, such a form of instruction is required by the circumstances of its district. In accordance with the request of the Town Council, the Lords of the Committee of Her Majesty's Most Honourable Privy Council of Education have been pleased to sanction this form of instruction under clause 8 of the Technical Instruction Act, 1889, for the borough of Sheffield, and this minute will be laid before Parliament in accordance therewith.

**New Business.**—Messrs. Pollock and Macnab, of the Britannia Iron and Engine Works, Hyde, near Manchester, announce that they have opened a new department in their business, that of electrical engineering. They have engaged as practical superintendent a specialist of large experience in some of the largest electrical engineering establishments in the Kingdom, and are therefore in a position to make electrical machinery and plant for electric lighting. They solicit a visit to see the plant they have put down for themselves.

**Electric Lighting Orders.**—Mr. O. V. Morgan asked the President of the Board of Trade whether the effect of the provisions which the Board had inserted in electric lighting orders now before Parliament, authorising local authorities to transfer their undertakings, would be practically to confer upon the Board of Trade powers to perform functions heretofore exercised by Parliament, and also deprive the public of the means that they now had of resisting any such transfer by appearing before a Parliamentary Committee where evidence was taken upon oath; and whether the Board would have the power to administer an oath if the functions of Parliament were so vested in that department. Sir M. Hicks-Beach: Section 11 of the Electric Lighting Act, 1882, provides that "no local authority, company, or person shall by any contract or assignment transfer to any other company or person or divest themselves of any legal powers given to them, or any legal liabilities imposed on them by this Act, or by any license, order, or special Act, without the consent of the Board of Trade." The provisional orders granted under the Act referred to require that public notice of the proposed transfer shall be given, and the transfer cannot be made without the consent of the Board of Trade, by whom the deed of transfer must be approved, and who will make any enquiries that they may consider necessary in the interests of the public. The Board of Trade would have no power to administer an oath. With regard to the merits of the clause, I wish to point out that the local authorities, who are representatives of the ratepayers, ought to be the best judges of their interests in matters affecting the lighting of the town.

**The Halifax and Bermuda Cable.**—A cablegram has been received by the Halifax and Bermuda Cable Company from the ss. *Westmeath*, in lat. 35° 11 min., long. 64° 7 min., stating that at noon on the 29th inst. 623 knots of the cable had been paid out, and that the steamer was now well past the influence of the Gulf Stream. Weather fine and everything satisfactory. The cable was completed on Tuesday last, and Messrs. W. T. Henley's Telegraph Works Company, Limited, are to be congratulated on the success they have met with in laying the new cable. A large number of soundings were taken, the bottom being found even and quite satisfactory; the greatest depth ascertained was 2,820 fathoms. The paying out of the cable was commenced on Wednesday, the 25th ult., and the ship arrived off Bermuda at noon on the 30th.

**New Companies.**—We understand that no less than 100 new companies have been registered during the past week. As may be seen in our columns a goodly proportion are electrical.

**A Financial Paper's Views.**—The *Financial Times*, speaking of the Okonite scheme, says:—"Before English capitalists rally round a concern intended to combine an American with an English business, they will want something a little more satisfying than a report by one of the English vendors on the American property, and by the American vendor on the English property, and those furnished by Mr. F. L. Rawson and Mr. F. Cazenove Jones respectively are the sole grounds on which the International Okonite Company bases its appeal to the public."

**More Newspaper Science.**—In the evening edition of yesterday's *Standard* it is gravely asserted that the power of the electrophonoscope to reproduce images is due to the employment of selenium, "whose capacity to transmit sunlight pictures has long been known to scientific men." If it is not too expensive, says our daily contemporary, we shall ere long find it in every office where a telephone is employed. We thought that the *D. T.* and another were the only papers which Messrs. Hughes, Preece and Stroh had fooled, but it is painfully evident that the "Technical and General News Agency," to which we referred last week, is more than ever a necessity of the *Times*.

**Manufacture of Double Carbon Lamps.**—The Brush Company, of Cleveland, has obtained an injunction against the Sperry Electric Company covering the manufacture or use of double carbon lamps. This is the fourth decree obtained by the Brush Company on this patent.

**Okonite.**—In 1886 a Mr. Smith, who was exhibiting in London the manufacture of okonite, gave a piece of the material to an electrical firm, who submitted it to a well-known analyst, whose report was as follows:—

Rubber	...	...	...	49.60	per cent.
Sulphur	...	...	...	5.30	"
Lamp Black	...	...	...	3.20	"
Zinc Oxide	...	...	...	15.50	"
Litharge	...	...	...	26.30	"
Silica	...	...	...	0.10	"
				100.00	

**Personal.**—Mr. Charles F. Quicke, works manager of the establishment of Messrs. Immisch, electrical engineers, of Kentish Town, was installed Worshipful Master of the Chislehurst Lodge of Freemasons, No. 1,531, at Chislehurst, on Saturday last, in the presence of a large number of metropolitan brethren.

**The Electrophonoscope.**—"This remarkable instrument will be exhibited for the first time at the Post Office Jubilee *soirée* at the South Kensington Museum. It is the joint invention of Prof. Hughes, F.R.S., Mr. Preece, F.R.S., worked out by Mr. Ströb, and Mr. Roberts, one of the Post Office officials. It solves the question of visual telegraphy. The sender of a message from a distant station appears in person before his correspondent, and with a telephone it is possible not only to speak to him, but to see him, and to watch the expression of his features. It is a perfect complement to the telephone, and will illustrate what telegraphy is likely to be in 1990." The above is the official description of the apparatus, which we have dealt with—we hope as it deserves—on another page.

**Electric Lighting in St. Pancras.**—Prof. Robinson has extended the time for receiving tenders for the various contracts. At a recent meeting of the vestry a letter was read which stated that the County Council had decided to advance the vestry a loan of £10,000.

**The Institution of Electrical Engineers.**—The Secretary sends us the following communication:—"Referring to the circular in regard to the Edinburgh meeting, issued by me to members of the Institution on the 25th ult., to which you were good enough to draw attention in your columns, I shall feel greatly obliged by your mentioning in your next issue that both the London and North-Western and the Midland Railway Companies have consented to issue to any of our members who may be proceeding to the meeting return tickets of any class, available for eight days, at the same reduced price as has been agreed to by the Great Northern Railway Company, viz., at a single fare and a quarter. The tickets will be issued from any of the stations of these companies' lines on production of a note signed by me, respecting which I shall in a few days issue to all who may have intimated their intention to attend the meeting, and who already number over one hundred, a circular, accompanied by a programme of the proceedings.

**Hammersmith and Fulham Electric Lighting.**—At a meeting of the London County Council on Tuesday last, the Parliamentary Committee reported that the Board of Trade had intimated to the Parliamentary agents that this order would not be proceeded with.

**Electrical Plant.**—Mr. Lea's successor, as editor of this monthly trade journal, is Mr. E. R. Dolby, A.M.I.C.E.; this gentleman has, on various occasions, contributed technical descriptions of electrical apparatus to the columns of the *REVIEW*, and we wish him prosperity.

**Admiral Colomb to be Rewarded.**—Lord G. Hamilton stated in the House of Commons on Tuesday, that the Government had decided to offer Admiral Colomb a further sum of £2,000 for his services in connection with the flashing signals used in the Navy.

**A Slight Drop.**—In the Fowler-Waring mains, on which the Deptford central station at present depends, the loss, with the load now in use, amounts to 1,200 volts.

**The Brighton Electric Light Wire Accident.**—On the appeal of the Brighton Electric Light Company against the damages awarded to Mrs. Garman for the death of her husband, the damages were reduced to £500.

**Cable Manufacture in Italy.**—Messrs. Pirelli & Co., whose works last year were almost at a standstill, are negotiating with the Italian Government for another cable which it is proposed to lay in Italian waters.

**The Electric Light in Preston.**—Provisional orders were issued on Wednesday morning authorising the National Electric Supply Company and the Lancashire and Cheshire House-to-House Electricity Company to supply various parts of the borough of Preston with electricity. These orders have yet to receive the sanction of Parliament.

**Personal.**—Mr. A. E. Mavor, M.I.E.E., at present electrical engineer to Messrs. Denny & Brothers, Dumbarton, has been appointed general manager of the Fowler-Waring Cables Company, Limited, of 85, Queen Street, Cheapside.

**Telpherage at Edinburgh.**—The telpher line at the Edinburgh Exhibition was opened last week on the occasion of the visit of the Lord Mayor of London. It has been made by the Electric Construction Corporation, who are, we understand, engaged upon a telpher line through the Via Flaminia, Rome, which is expected to be opened very shortly.

**Elmore's Patent Copper Depositing Company.**—This company has now on exhibition, at 56, Queen Victoria Street, an interesting collection of specimens of seamless copper tubes, seamless copper cylinders, high conductivity wire and other products made under the company's patents upon a commercial scale at their works in Leeds. Some tests of copper deposited by this process were recorded in our issue of June 14th, 1889.

**Electric Launch Building.**—We are informed that the boat building business hitherto carried on at Strand Works, Chiswick, by Mr. Sargeant, the builder of the well known *Viscountess Bury*, has been acquired by Woodhouse and Rawson United, Mr. Sargeant's services being retained as manager of that department of the business.

## NEW COMPANIES REGISTERED.

**Thetford Electric Light and Power Co., Limited.**—Capital £5,000 in £10 shares. Objects: To carry on in all branches the business of an electric light and power company. Signatories (with one share each): \*C. Burrell, jun., \*R. G. Burrell, \*F. J. Burrell, J. Houchen, F. V. Houchen, T. Lumley, all of Thetford, Norfolk; \*W. Jackson, Knottingley, York. The signatories denoted by an asterisk are the first directors; qualification £50 in shares or stock. The company in general meeting will determine remuneration. Registered 23rd inst. by Mr. R. Jordan, 120, Chancery Lane. Registered offices, St. Nicholas Street, Thetford, Norfolk.

**International Okonite Company, Limited.**—Capital, £340,000 in £10 shares. Objects: To manufacture insulated and other wires and cables for telegraphic, telephonic, and other purposes, and for such purposes to adopt an agreement with Woodhouse and Rawson

United, Limited. To carry on business as electricians. Signatories (with 1 share each): F. Spooner, 83, Rendlesham Road, Lower Clapton; J. Beaumont, 9, Daneville Road, Camberwell; H. E. Smith, 26, Park Place, Leyton; H. C. Newton, 121, Avenell Road, N.; J. S. Stornden, 60, Moray Road, N.; W. Daune, 6, Lexham Gardens, W.; A. Stevens, 4, Trafalgar Square. The first English directors will be appointed by the subscribers; remuneration, £1,500 per annum, and in addition 3 per cent. on all net profits other than profits derived from the American branch of the business. There will be a committee of management in America, the first members of which are F. Cazenove Jones, H. Durant Cheever, W. L. Candee, J. H. Cheever, and H. Martin; remuneration, 5 per cent. on all net profits resulting from the American branch of the business. Qualification for subsequent directors, 50 shares or £500 stock. Registered 24th ult. by Parker, Jarrett and Parker, St. Michael's Rectory, Cornhill.

**S. Z. de Ferranti, Limited.**—Capital, £100,000 in £10 shares. Objects: To purchase any business or patents relating to electricity. Signatories (with 1 share each): \*S. Z. de Ferranti, \*H. P. Sparks, Charterhouse Square; \*F. Ince, J. B. Ince, St. Benet Chambers, Fenchurch Street; T. W. Hunter, 2, Dashwood Road, Stroud Green; A. Wright, 3, Clermont Road, Brighton; H. W. Kolle, Egremont, Tulse Hill. The first three signatories are appointed directors; qualification, 100 shares; the company in general meeting will determine remuneration. Registered 26th ult. by Ingledew, Ince and Colt, St. Benet Chambers, Fenchurch Street.

**Woolwich District Electric Light Co., Limited.**—Capital £10,000, in £1 shares. Objects: To carry on the business of an electric light company in all branches. Signatories (with 20 shares each): J. T. Randall, A. W. Mellish, Robt. Webb, R. B. Dale, G. H. Campbell, G. Whale, W. H. Pryce, all of Woolwich; J. R. Jolly, J.P., Plumstead. Registered without special articles by G. Whale, 54, Cannon Street.

**Canterbury Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on the business of electrical engineers and suppliers of electrical apparatus, mechanical and chemical engineers. Signatories (with 1 share each): Emile Garcke (Manager and Secretary Brush Electrical Engineering Company, Limited); J. L. Raworth (engineer); W. C. Mann, R. A. Dawburn (electrical engineer), W. M. Mordey (electrician), R. Percy Sellon, W. Geipel (electrical engineer), all of 112, Belvedere Road, Lambeth. Most of the regulations of Table A of the Companies' Act, 1862, apply. Registered 28th ult. by Sydney Morse, 4, Fenchurch Avenue, E.C.

**Cardiff Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on the business of electricians in all branches. In this and following six companies the signatories are the same as in the preceding company. Registered 28th ult. by Sydney Morse, 4, Fenchurch Avenue.

**Henley Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on business as electricians. Registered 28th ult. by Sydney Morse, 4, Fenchurch Avenue.

**Ipswich Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on business as electricians. Registered 28th ult. by Sydney Morse, 4, Fenchurch Avenue.

**Loughborough Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on business as electricians. Registered 28th ult. by Sydney Morse.

**Manchester Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: Electricity in all branches. Registered 28th ult. by Sydney Morse.

**Penzance Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on business as electricians in all branches. Registered 28th ult. by Sydney Morse.

**Weymouth Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: Electricity in all branches. Registered 28th ult. by Sydney Morse. The registered offices of the above companies are at 112, Belvedere Road, Lambeth.

**Kidderminster Electric Light and Power Supply Company, Limited.**—Capital £1,000, in £1 shares. Object: To carry on at Kidderminster or elsewhere the business of an electric light and power company in all branches. Signatories (with 1 share each): C. S. Peach, 8, John Street, Adelphi, architect; E. Bax, Eltham, Kent; C. Roberts, C.E., 6, Gray's Inn Place; J. R. Cleave, Hotel Windsor, Victoria Street, S.W.; E. J. Jennings, 13, Victoria Street, engineer; R. Thicknesse, 11, Abchurch Lane; T. B. D. Cooper, 5, Victoria Street, engineer. The subscribers are to appoint the first directors. Qualification, £50 shares or £50 stock. Remuneration, £200 per annum to the chairman, and £100 per annum to each director. Registered 28th ult. by Fox and Thicknesse, 11, Abchurch Lane.

**East Coast Electric Light and Power Company, Limited.**—Capital £1,000, in £1 shares. Objects: To carry on in the towns of the East Coast or elsewhere the business of electric lighting. The signatories for one share are the same as in the preceding company, and the same arrangements for directors also apply. Registered 28th ult. by Fox and Thicknesse.

**Devonshire Electric Light and Power Company, Limited.**—Capital £1,000, in £1 shares. Objects: To carry on in Devonshire or elsewhere the business of electric lighting in all branches. The signatories are the same as in the two preceding companies, and the same regulations as regards directors also apply. Registered 28th ult. by Fox and Thicknesse.

**Camberwell and Islington Electric Light and Power Company, Limited.**—Capital, £1,000 in £1 shares. Objects: To carry on in the parishes of Camberwell and Islington the business of electric lighting. The signatories of the three preceding companies take one share each in this company. The same regulation for directors also apply. Registered 28th ult. by Fox and Thicknesse.

**Stamford Hill, Tottenham and Edmonton Electric Light and Power Company, Limited.**—Capital, £1,000 in £1 shares. Objects: To carry on in the neighbourhoods mentioned in title the business of electric lighting. The signatories of the four preceding companies subscribe for one share each in this company, and the same arrangements for directors apply. Registered 28th ult. by Fox and Thicknesse.

**Provincial Electric Light and Power Supply Company, Limited.**—Capital, £1,000 in £1 shares. Objects: To carry on electric lighting business in the provinces. Signatories as in five preceding companies. Registered 28th ult. by Fox and Thicknesse.

**New Cadogan and Belgrave Electric Supply Company, Limited.**—Capital £1,000, in £10 shares. Objects: To take over the business and undertaking of the Cadogan Electric Light Company, Limited. Signatories (with 1 share each): \*A. Greenwood, 8, Cavendish Road, Leeds; \*Lieut.-Col. A. W. Thynne, 50, Cadogan Square; J. S. Sayer (electrical engineer), 37, Drayton Gardens, South Kensington; G. Chapman, 48, Luiver Road, Fulham; G. Hogger, Hether Green, Lewisham; C. Bonsor, 8, Vincent Square, Westminster; A. S. Batley, Thames Ditton. The signatories denoted by an asterisk are the first directors; qualification, £100 in ordinary shares; the company in general meeting will determine remuneration. Registered 30th ult. by Brook, Freeman & Batley, 89 Chancery Lane.

**Weston-super-Mare Electricity Supply Company, Limited.**—Capital £100, in £1 shares. Objects: To carry on business as electricians and electrical engineers in all branches. Signatories (with 1 share each): H. G. Massingham, Bath Electric Light Works; Emile Gareke, J. C. Raworth, R. A. Dawburn, W. Geipel, W. M. Mordey, and R. Percy Sellon, all of 112, Belvedere Road, Lambeth. Most of the regulations of Table A of the Companies' Act, 1862, will regulate the affairs of

the company. Registered 30th ult. by Sydney Morse, 4, Fenchurch Avenue; office, 112, Belvedere Road.

**Bristol Electricity Supply Company, Limited.**—Capital, £100 in £1 shares. Objects: To carry on business as electricians in all branches. The signatories are the same as in the preceding company. Registered 30th ult. by Sydney Morse, 4, Fenchurch Avenue, E.C.

**Northern Counties Electric Light and Power Supply Company, Limited.**—Capital, £1,000 in £1 shares. Objects: To carry on in Northumberland and elsewhere the general business of an electric light company in all branches. Signatories (with 1 share each): Ralph Thicknesse, 11, Abchurch Lane; E. J. Jennings, 13, Victoria Street; E. W. Monkhouse, 3, Robertson Terrace, Hastings; F. B. Nicholson, 9, St. Petersburg Place, Bayswater; F. W. Stenlake, 13, Victoria Street; A. F. Barter, 60, Hercules Buildings, Lambeth; Wm. Jennings, 59, Fleet Street. The signatories are to appoint the first directors; qualification, £50 in shares or stock; remuneration, chairman, £200 per annum; each director, £100 per annum. Registered 30th ult. Solicitors, Messrs. Fox and Thicknesse, 11, Abchurch Lane.

**Paddington and Bayswater Electric Light and Power Supply Company, Limited.**—Capital, £1,000 in £1 shares. Objects: To carry on electric lighting in the parish of Paddington and elsewhere. Signatories (with 1 share each): F. B. Nicholson, 7, St. Petersburg Place, Bayswater; C. Jennings, Montpelier Road, S.E.; E. J. Jennings and F. A. Stenlake, 13, Victoria Street; C. Baizley and W. R. Adams, 59, Fleet Street. The arrangements for directors are the same as in the preceding company. Registered 30th ult. Solicitors, Fox and Thicknesse, 11, Abchurch Lane, E.C.

**District Messenger Service and News Company, Limited.**—Capital £200,000 in £5 shares. To manufacture and supply electrical appliances for transmitting messages, signals, and for other purposes, and to purchase certain letters patent upon terms of an unregistered agreement with Charles Tweed Russell. Signatories (with 1 share each): H. G. Asten, R. B. Smith, A. Lovis, 50, Lime Street; H. Osbornler, 24, Cedars Road, Clapham; G. Macmaldrew, 26, Woburn Place; C. Tweed Russell, 18, Southwell Gardens, South Kensington; W. H. Williams, 60, Felenstowe Road, Kensal Green. The signatories are to appoint the first directors; qualification, £500 in shares; remuneration, £250 per annum each, with £50 additional for the chairman. Registered 30th ult. by Ashurst, Morris, Crisp & Co., 6, Old Jewry.

---

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

---

**British Electric Light Company, Limited.**—An agreement of 19th ult. between this company and John Muirhead and Latimer Clark, cites that the two latter are unsecured creditors of the company for £800, and have agreed to accept 40 fully paid preference shares in satisfaction thereof.

**Northern District Telephone Company, Limited.**—At an extraordinary meeting of this company, held at Oxford Court, Cannon Street, on the 15th May, special resolutions were passed approving an agreement for the sale of the business and property of the company to the National Telephone Company, Limited, and with a view to giving effect to the same to wind up voluntarily, Mr. Thomas Abercrombe Melton be appointed liquidator. The resolution was confirmed on the 12th ult., and was filed on the 28th ult.

**Northampton Electric Light and Power Company, Limited.**—The annual return of this company, made up to the 17th ult., was filed on the 24th ult. The nominal capital is £50,000, divided into 10 A and 49,990 B shares of £1 each. The whole of the former

and 10,000 of the latter are taken up. Upon the B shares the full amount has been called, the calls paid amounting to £4,927, and unpaid to £5,073.

**Electrical Engineering Corporation, Limited.**—At an extraordinary general meeting of this company, held at 3, Prince's Mansions, Victoria Street, on the 8th May, certain alterations were made in the articles of association, one of these fixing the qualification of a director at £500 in shares. The special resolutions were confirmed on the 6th June, and were duly filed on the 23rd June.

**General Electric Power and Traction Company, Limited.**—An agreement of 22nd May with the Electric Construction Corporation provides for the acquisition by this company of certain license of patents for £30,000 in fully paid ordinary shares.

**Railway Electrical Contractors, Limited (in Liquidation).**—The registered office of this company is now situate at 1 and 2, Great Winchester Street.

**City of Westminster Electrical Syndicate.**—The registered office of this company is situate at 4, Victoria Mansion, Victoria Street, Westminster.

**New Electric Fire Lighter Company, Limited.**—The registered office of this company is situate at the Works, Marsh Gate Lane, Stratford, E.

## LEGAL.

**Chatenay v. the Brazilian Submarine Telegraph Company.**—This case came before Mr. Justice Day, sitting without a jury, on Wednesday. The plaintiff, who resides at Rio, said he was, at the time of his mother's death, the registered holder of 50 shares in the defendant company, whose offices are in London, but since then his name had been removed from the register of shareholders without his consent, and some other person's name had been substituted as the holder of the said shares. The plaintiff had given a power of attorney to his agent, Mr. Bruyere, of London, to act for him, and the question his Lordship was asked to decide was whether Brazilian or English law governed this power of attorney.

Mr. H. D. Greene, Q.C., and Mr. Alexander Young were counsel for the plaintiff; Mr. R. B. Finlay, Q.C., Mr. Graham, and Mr. Calvert were counsel for the defendant.

Mr. GREENE said the defendant wanted to issue a commission to Brazil to take evidence as to the meaning of this alleged power of attorney, contending that Brazilian law would govern the operation of it in this country. Mr. Chatenay, in his deposition, said he had never received dividends on the shares direct, but through his agent in London. Plaintiff was trustee for other members of his family, and he had never authorised anyone to transfer these shares. The learned counsel submitted that under these circumstances Mr. Bruyere's rights under the power of attorney were regulated by English law.

Mr. FINLAY insisted that the document having been executed in Brazil by the plaintiff, a resident in Brazil, it must be governed by the Brazilian law.

His LORDSHIP, at the conclusion of the arguments, held that the power of attorney was a general power, and must be governed by the laws of the country in which it was exercised.

the company's revenue was secure. The amount brought forward last year amounted to £4,878 4s. 8d. as against £1,215 9s. 11d. in 1888, or an increase of £3,662 14s. 9d. The total expenses in 1889 were £21,155 9s. 8d., and in 1888 they were £20,016 0s. 7d., so that there was an increase of £1,139 9s. 1d., which was due almost entirely to the causes he had mentioned. The hire of cable repairing ships—viz., £1,780 3s. 1d., was charged to the current revenue account, and a balance of preliminary expenses, £750, was written off. A fair amount had been written off for depreciation of cable stock. The net result of 1888, after providing for expenses, interest, and a sinking fund for the redemption of 5 per cent. debentures, had been a dividend of 2½ per cent. per annum, £5,000 to repairs and renewals account, and £4,878 4s. 8d. carried forward. This time they declared a dividend of £5 per cent. for the year, and they charged repairs and renewals to the revenue account, and they carried to the general reserve fund the sum of £16,145 11s. The balance to the credit of repairs and renewals, £3,074 2s. 5d., has been carried to the general reserve fund, so that the interest on investments added to the general reserve fund amounted to £19,712 18s., fully invested. This, he thought, was a fulfilment of the promise made by him twelve months ago. In 1887 they had no dividend, in 1888 the dividend was 1½, in 1889, after the reconstruction of the Board, the dividend was 2½ per cent. He believed that the company was destined to play a very important part in the opening up of the "dark continent." Referring to the Telegraphic Conference lately held in Paris, he claimed that the result was on the whole that the cable companies held a higher position than probably they had ever done in the estimation of the public and continental governments. He admitted they were fairly treated on the whole, although the tendency was to reductions, in which they must bear their share, whilst they consoled themselves with the thought that reductions very often lead to increased traffic. He moved the adoption of the report and accounts, and the declaration of a dividend, payable on and after that date, of 6s. 6d. per share, free of income tax, making, with the interim dividend already paid, a total distribution for the year of 5 per cent.

The motion was carried unanimously, Sir John Pender and Mr. R. K. Gray were re-elected directors, the appointment of Mr. J. Denison Pender as a director was confirmed, and Messrs. Deloitte, Dever, Griffiths & Co. were reappointed auditors of the company, and with a vote of thanks to the chairman and directors the proceedings came to a close.

## The National Telephone Company, Limited.

THE report of the directors to be presented at the tenth ordinary general meeting, to be held at the Cannon Street Hotel on Friday, 11th July, at 12 o'clock, states:—The directors have the pleasure of submitting to the shareholders the accounts for the year ending 30th April, 1890, showing a balance to the credit of net revenue account of £183,375 19s. 7d., after providing for the amalgamation expenses, and the accrued interest on the debentures and new shares. Of this amount the sum of £66,131 5s. has been absorbed by the payment of an interim dividend on the preference and ordinary shares at the rate of 6 per cent. per annum for the first six months of the year. The directors propose to pay a further dividend on both classes of shares at the rate of 6 per cent. per annum for the last half of the year, which will absorb a further sum of £66,131 5s., and leave a balance still on hand of £51,113 9s. 7d. In view of the near expiration of the company's patents, the directors think it prudent to strengthen the reserve account, and they propose, under article 113 of the articles of association, to transfer to this account £40,000, leaving £11,113 9s. 7d. to be carried forward to next year. The extension of the company's business during the past year has been very satisfactory, the gross annual rental from exchange, trunk, and private lines having increased from £343,544 1s. 1d. on the 30th April, 1889 (prior to the amalgamation), to £392,541 19s. 1d. on the 30th April, 1890, an increase in the year of £48,997 18s. The important trunk lines connecting London with the principal towns in the Lancashire, Yorkshire, and Midland districts were completed as far as Edgware in January last, and the service proved to be perfectly clear and distinct. Some difficulty was then experienced in running the wires through to London, which was not overcome in time to have the connection completed before the issue of this report. The directors have every confidence that the communication between London and the North will be established by the end of this month. A large number of additional trunk lines connecting various towns in the provinces have also been commenced during the year, many of which have been completed. These trunk lines supply a much-felt public want, and will add greatly to the strength of the company. The directors believe it most important to continue the policy of developing and improving the company's system, and of giving greater facilities to the public. The capital required for this purpose the directors propose to raise by the issue of debenture stock or preference shares, as may be found best for the interests of the company. The accrued rental for the year ending 30th April, 1890, was £364,704 17s. 5d., an increase of £45,162 over the accrued rentals of the National, United and Lancashire and Cheshire Companies for the year before the amalgamation. The working expenses for the year ending 30th April, 1890, amount to £148,457 0s. 9d., being 40·7 per cent. on the accrued rental, whilst the working expenses of the three companies before the amalgamation were

## CITY NOTES, REPORTS, MEETINGS, &c.

### The West African Telegraph Company, Limited.

THE fifth ordinary general meeting of the shareholders was held at Winchester House on Thursday, the 3rd inst., to receive the directors' report and accounts, &c., for the year ending 31st December, 1889 (printed in our last issue).

Sir John Pender, K.C.M.G., who presided, said that several new stations for the company's joint working arrangements had been established in the year under review, and that a new cable had been laid between Bonny and Principé. As regards the net result of the year's working, compared with the previous year, the gross revenue amounted to £64,661, as against £55,315, or an increase of £9,346, almost entirely derived from the traffic with South Africa. Communication between the company's line and Cape Town was established on the 4th June last, so that they had only had the benefit of the new traffic for seven months. The South African traffic was worked under a joint purse agreement between the Eastern, the Eastern South African, the Brazilian Submarine, the Spanish National, and this company; and so long as communication was maintained by either coast

47·7 per cent. This saving of 7 per cent. is owing to reductions of working expenditure rendered possible by the amalgamation. The directors have taken over the business of the Northern District Telephone Company, Limited, which is now merged in this company. The Postmaster-General not having given notice to purchase the company's business under the power reserved by the terms of his licence, is not now entitled to do so for another period of seven years. The auditors, Messrs. Welton, Jones & Co., retire, and are eligible for re-election.

### The Electric Engineering Company of Ireland.

THE first statutory meeting of the Electric Engineering Company of Ireland was held last week in the board room, Dawson Street, Sir Howard Grubb, F.R.S., presiding. The company was registered on the 5th March, 1890. The prospectuses were issued to the public on the 8th, and 6,800 £2 shares were allotted to the public and vendors.

The Chairman said the company had obtained some good contracts, and the great number of estimates which they had been asked to furnish not only gave good promise for the future, but showed very clearly that the establishment of such a company was a necessity in Dublin. However, there were many causes to check its immediate development. The acceptance of many of the estimates applied for had been made contingent on the starting of the general electric lighting scheme proposed by the Corporation of Dublin, the arrangements for which were not quite complete, and the period within which it would be available for the general public was therefore uncertain. If no such scheme had been contemplated, many business houses would be prepared to erect private installations; but so long as the matter remained uncertain, they could not expect intending users to lay out money on private installations. Again, the public required to be further educated as to the advantage of electric lighting. Up to the present the question which users invariably asked was simply, Will my gas or my electric light bill be the heavier at the end of the year? But he thought the time was coming when in comparing the relative advantages of the systems the public will learn to place the doctors' bills, deterioration of furniture, decorations, books, &c., on the right side of the account, and perhaps by that time would be getting a little tired of the oft-repeated story of the electrically-frizzled horse. Perhaps he might be allowed to mention one specific case which had come under his own immediate ken. In an institution in which he frequently had business, he happened to know that a sum of £50 was added to the decorator's estimates for the purpose of doing some gilding to the ceiling and cornices of one particular room. Judging by the effect already produced, though the gas was seldom used in that room, this would not last for many years, whereas if electric light were in use it would be good for 50 years; also, he understood that a considerable sum of money would have shortly to be expended in the rebinding of books, the backs of which had been completely destroyed by the products of the gas. In this particular case it would certainly have been much cheaper to have used electric light than gas, even if the latter had been supplied without any charge whatever. Again, electric light installations had been frequently undertaken by firms wholly without the required technical knowledge or the means of obtaining it, result being that the work has been done in an inefficient manner. In this company there was no mixing up of electric light with any other business. They had an efficient staff of electric engineers, all of whom had held positions under some of the largest and best known electric light companies now working, in addition to which, in case of any work of great magnitude, they had the advantage of the experience of one of the oldest, largest, and most successful electric lighting companies in the world—viz., the Brush Corporation of London. The temptation in the case of inexperienced firms, particularly when there is much competition, was to promise too much, and to cut down the estimates as closely as possible to secure the order. Their board did not believe in the wisdom of endangering the future reputation of the company for the sake of a possibly increased show of work in the present; nor did they propose to undertake work (for advertising or other such purposes) which would not pay a reasonable profit. In conclusion, the chairman pointed out the advantages to health from the use of electric light instead of gas, and quoted from an article which appeared in the *Daily News*, and in which it was stated that since the installation of electric light in the Post Office, there had been a saving of £600 a year effected, owing to the decrease of leave of absence to the members of the staff who were ill.

Sir H. Grubb was re-elected chairman, and Messrs. George F. Fitzgerald, Thomas J. Haslam, Emile Garcke, David Sherlock, and J. H. North directors, and a sum of £200 per annum was agreed to be set apart as the remuneration for the directors other than the managing director.

Messrs. Harrison and Nichols were elected auditors to the company.

A Shareholder asked why the contract for the lighting of the New Science and Art Museum had not been obtained by the company?

The Chairman said the contract had been closed before the company was incorporated.

M. Emile Garcke, secretary of the Brush Electric Company, London, was moved to the second chair, and a vote of thanks was passed unanimously to Sir Howard Grubb for presiding.

Sir Howard Grubb having responded, the proceedings terminated.

### Maxim-Weston Electric Company, Limited.

A MEETING of the shareholders of this company was held at Winchester House, on Wednesday, to consider the present condition of the company. Our own reporter was refused admission, but we are enabled to give the following report:—

The Chairman (Mr. Gooding), after giving some facts as to the value of the stock, machinery and assets of the company, stated that there had been a great reduction in the working expenses. The directors had not taken, and did not intend to take, any fees pending the decision in Mr. Watt's action. In the past the electric lighting companies had paid enormous sums for patents which were of little value, and that had rendered difficult their successful development. The Maxim-Weston Company had several complete installations, and were supplying plant, &c., not only in this country, but in Ireland, and were continually receiving enquiries for tenders, but it was somewhat difficult to carry on negotiations because they were hampered for want of capital. The directors have shown great faith in the company and he hoped the shareholders would do the same, and find the necessary money to carry the company on successfully.

Mr. Hodgson (a new director), on being asked his opinion of the company, stated that since he had been on the board he had given a great deal of time and consideration to its affairs, and believed that, without any great outlay, they could carry out the electric lighting on a large scale very successful. He should have no hesitation in subscribing more capital.

Several shareholders, after a short discussion, expressed their willingness to contribute in the way of debentures.

The Chairman stated that he and the other directors were prepared to do likewise. The meeting was of an informal character and no resolution could be passed, but the directors and a number of shareholders having agreed to subscribe capital it would, he said, be done by way of floating debentures with security on the works of the company.

**The India-Rubber, Gutta-Percha, and Telegraph Works Company, Limited.**—A half-yearly general meeting of the company will be held at the Cannon Street Hotel, London, on Thursday, the 10th inst., at 12 o'clock noon, for the purpose of obtaining the sanction of the shareholders to the payment of an interim dividend of 5 per cent., or 10s. per share, free of income tax. The company's share register will be closed till the 10th inst.

**The Eastern Extension, Australasia, and China Telegraph Company, Limited.**—This company notifies that the coupon on their 5 per cent. Australian Government subsidy debentures, due on July 1st, will be paid on and after that date, at the banking house of Messrs. Barclay, Bevan & Co., 54, Lombard Street, E.C. The directors have also declared an interim dividend of 2s. 6d. per share, tax free, payable on the 15th inst.

**The United Electrical Engineering Co., Limited, in Liquidation.**—By notice in the *Gazette*, June 27th, creditors of the company are required on or before July 26th, 1890, to send their names and addresses, particulars of their debts or claims, and the names and addresses of their solicitors (if any) to Alfred Sydney Gedge and William Leonard Madgen, the liquidators, No. 3, St. James Street, Bedford Row, Middlesex.

**The Automatic Electric Railway Signal Company, Limited.**—By an Order of the High Court, Chancery Division, dated 21st June last, on the petition of Blakey, Emmott and Co., Limited, of Square Road, Halifax, York, creditors of the company, it was ordered that the winding up of the company be continued, subject to the supervision of the Court.

**Western Counties and South Wales Telephone Company, Limited.**—At an extraordinary meeting of this company, held on Friday last, the resolution passed at the meeting of May 30th, for the alteration of the articles of association, was confirmed.

**The American Bell Telephone Company.**—The directors have declared an extra dividend of 6 per cent., in addition to the regular 3 per cent.

### TRAFFIC RECEIPTS.

The Cuba Submarine Telegraph Company. The receipts for the month of June were £3,300, as compared with £3,337 in the corresponding month of last year. The receipts for the month of March, estimated at £4,000, realised £4,018.

The Direct Spanish Telegraph Company, Limited. The estimated receipts for the month of June were £2,085, against £1,600 in the corresponding period of last year.

The Eastern Extension, Australasia and China Telegraph Company, Limited. The receipts for the month of June, 1890, amounted to £43,198, an increase of £3,848.

The Eastern Telegraph Company, Limited. The receipts for the month of June, 1890, amounted to £51,019, an increase of £6,214.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending June 27th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,216.

The West Coast of America Telegraph Company, Limited. The gross earnings for the month of June, 1890, were £5,475.

West India and Panama Telegraph Company, Limited. The estimated traffic receipts for the half month ended the 30th June, are £3,127, an increase of £353.

THE LINEFF TRAMWAY MAGNETIC  
CONDUCTOR.

ALTHOUGH we have described the Lineff system in a previous issue, we have been requested to insert the following in our present issue:—

The new Lineff conductor for tramways is the first which has practically taken advantage of the force of magnetism, in closing the circuit in electric traction. The surface rails are laid in lengths of about 3 feet in a bed of asphalt, and as they are without any groove, and have their upper surface flush with the roadway, they cannot form any obstruction to traffic either along or across the track. In point of fact they are hardly to be distinguished from the roadway itself.

Each of these rails is bolted by means of brass bolts and distance pieces to a piece of tee iron of equal length, so placed as to have its base on the same level as that of the surface rails, at a distance from it of about a quarter of an inch. The tee iron being of lower height than the surface rail does not appear at all on the roadway, being completely buried in the asphalt surrounding the whole. One end of the tee iron projects beyond the corresponding end of the surface rail, so that the rails when laid in position break joint with one another all along the road.

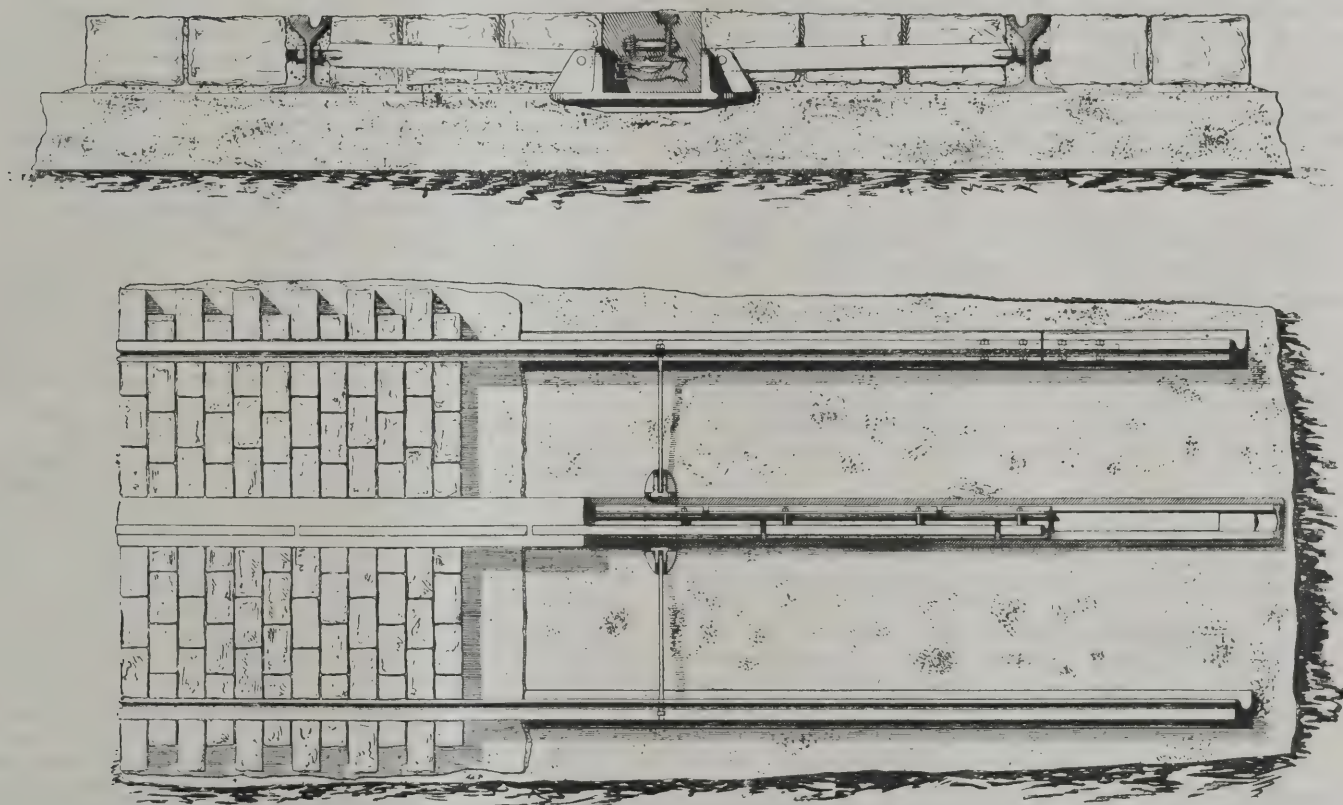

The two irons together form a roof to a continuous channel  $3\frac{1}{2}$

## ROYAL AGRICULTURAL SHOW.

THE annual show of the Royal Agricultural Society of England was held at Plymouth from the 21st to 27th June. In the machinery department were a number of exhibits possessing considerable interest as illustrating the increasing attention given by makers of engines and electrical machinery to the special requirements of country houses and large farms. Amongst them the premier place must be assigned to the joint exhibit of the *Priestman* oil engine and *Mr. Newton's* collection of machinery and apparatus for electric lighting and transmission of power, including the "Taunton" dynamo. The stand itself was ornamented with art drapery, and fitted up with a variety of lamps and shades. It attracted crowds of investigators, many of

## MAGNETIC CONDUCTOR FOR TRAMWAYS : LINEFF'S PATENT.

## CENTRAL ARRANGEMENT.

inches wide, formed by insulating tiles, on which the irons rest. This channel contains the bare copper main, shown in the drawing as a flat strip, and on this rests a flexible hoop iron 3 inches wide, which is free to rise into contact with the lower flanges of the surface and tee rails, from which it is in its normal position distant about  $\frac{5}{16}$ th inch.

Each car carries underneath it an electro-magnet, each pole of which contains a solid iron wheel which runs on the surface rail. The distance between the pole pieces is slightly greater than the length of one section of the surface rail, so that the two poles are never on the same section.

The magnet is energised by the main current, the wire forming the coils being coupled in shunt with the motor circuit.

The magnetic lines emanating from the magnet poles pass into the surface rail. The section of this being insufficient to carry the whole of the magnetic lines, a large proportion of them leak across to the buried tee rails, and as the connection between each pair of rails (surface and buried) is of a non-magnetic material, the lines jump across the air space between the lower flanges. Opposite poles are consequently induced in each of the surface and tee rails under the immediate influence of the electro-magnet, and the leakage "cross" lines, being diverted through the strip of hoop iron lying immediately below the air gap, in their attempt to shorten themselves attract the hoop iron into contact with the bases of the surface and tee rails; both of which, as they are in electrical (though not in magnetic) connection assist in taking off the current.

whom made on this occasion their first acquaintance with the electric light and the method of its production. Everything was open to inspection, and from an educational point of view the exhibit was a most useful one. The oil engine run by Messrs. Priestman Brothers was a 2 H.P. horizontal, and the "Taunton" dynamo was a 30-lighter, a set of accumulators being also employed in order to illustrate their use. A portable oil engine, 11 H.P., mounted on wheels, with shafts, was also shown driving a thrashing machine, and convincing the spectators of its suitability for such purposes. Messrs. Priestman Brothers have been awarded the first prize at this show for a small farmer's motor, and we are glad to hear that they are busy with orders in hand for home and abroad for their oil engines which are rapidly coming to the front as a motive power. According to the catalogue there should have been exhibited at one of the stalls a self-regulating dynamo, 5 unit, suitable for transmitting power to a motor for driving dairy and other machinery on a

farm, as well as two electric motors suitable for driving farm machinery, made by *Mr. J. E. Veale, of St. Austell's*, but in reality only the dynamo was on view, and that not working. At the stand of *Messrs. Gilbert Gilkes & Co.*, amongst other turbines, one was shown operating a small Gülicher dynamo. Amongst the "new implements" a magnetic separator and dynamo was exhibited by *Mr. J. Harrison Carter*, intended to surmount the serious obstacles attending the use of old toothed bone mills or disintegrators arising from the frequent presence of iron with the bone.

*Messrs. John Fowler & Co., Leeds*, exhibited what they have named the "Yorkshire" engine, horizontal, compound, 12 H.P., fitted with automatic expansion gear on both cylinders controlled by one governor, and specially constructed for driving dynamos or other machinery requiring steady driving. Another engine specially constructed for the same purpose, and shown by *Messrs. Ransomes, Sims and Jefferies*, was a 10 H.P. compound "Undertype" with patent automatic expansion gear. At *Messrs. Robey & Co.'s* stand was a vertical high speed engine, with cylinder  $6\frac{1}{2}$  inches diameter by 6 inches stroke, working at a pressure of 80 lbs., a very suitable engine for small electric light installations or for ship lighting.

*Messrs. Davey, Paxman & Co., of Colchester*, exhibited an improved compound portable steam engine and an improved single-cylinder portable steam engine, both of which were selected by the jurors for driving the various machines sent for competition. This we consider a great compliment to the makers. The steady running of these engines leaves nothing to be desired. The makers have maintained for very many years (in spite of much opposition), that first rate results can be obtained with compound engines working without condensers, and the performance of the one at present under consideration fully establishes all their arguments in favour of this class of engine.

The boiler is of the locomotive type with an improved firebox. The engine is complete in itself, being built on a steel channel frame which is securely bolted to brackets on the boiler. By merely removing a few bolts the whole engine and frame can be lifted from the boiler, and if so desired, fixed and worked separately.

Both engines are fitted with the Paxman automatic gear which has gained a world-wide character by the way in which it controlled the engines used for electric lighting at the various exhibitions, and especially in Paris.

The compound engine works at a pressure of 140 lbs. and the nominal horse-power is 8 H.P. The high pressure cylinder is  $5\frac{1}{2}$  inches in diameter, and the low one 9 inches. These sizes are such that the powers developed by the cylinders, separately, are about equal when working with a fair load. The stroke is 14 inches.

The other portable engine exhibited by this firm, viz., the single cylinder one, is of a different pattern. The cylinder is bolted on to the firebox, and the crankshaft is supported by two brackets bolted to the barrel of the boiler. The barrel of the boiler is lagged and the cylinder steam-jacketed. This engine is nominally of 8 H.P. but it will work up to 20 H.P., the diameter of the cylinder being  $9\frac{1}{2}$  inches and the stroke 12 inches. Both these engines are mounted upon wrought iron carriages and supported by wrought iron wheels of a simple and very strong design. They consist of a number of spokes of wedge shaped loops of iron, the free ends of which are cast into the centre, the sides of which are rivetted together. A wrought iron rim is shrunk on and rivetted to the outside of the loops.

The Knight paraffin oil engine, shown for the first time at the Windsor show last year, was exhibited this year by the makers, *Messrs. Brown & May*, who call attention to the fact that this engine works without electricity, and as only one kind of oil is used for starting and working, the cost and trouble is reduced to a minimum. It is said to be well adapted for driving electric light machinery, especially where the saving of space is important. The Forward gas engine was also

on the ground, as well as the new gas engine (Fielding's patent), lately introduced by the makers, *Messrs. Fielding & Platt*. The special feature of this engine is said to be its simplicity, as it has fewer working parts than any other in the market. Its working is silent and regular and the wear and tear very slight.

## COUNTY COUNCIL AND ELECTRIC LIGHTING.

### NUMEROUS EXTENSIONS SANCTIONED.

#### LONDON ELECTRIC SUPPLY CORPORATION.

At the weekly meeting of the London County Council on Tuesday last week, in the County Hall, Spring Gardens (the Earl of Rosebery in the chair), Mr. T. B. Westacott, the Chairman of the Highways Committee, submitted a report recommending the council to sanction the laying of mains by several electric lighting companies. The various recommendations were approved without discussion. The committee reported that they had "considered a notice (Registered No. 90) from the London Electric Supply Corporation, dated 4th June, 1890, of intention to lay trunk mains from Cockspur Street through the Haymarket, Glasshouse Street, Vigo Street, Burlington Gardens, Cork Street, Clifford Street, and Bond Street, to the company's station at the Grosvenor Gallery, as shown upon a plan submitted with the notice. In some of these streets the St. James's and Pall Mall Electric Lighting Company has already laid low-tension mains, and it appears to your committee advisable that the proposed trunk mains of the London Company should be laid beneath these. There seems to be no objection to the works, provided that proper means are taken for the protection of the mains; and your committee recommend—'That the sanction of the council be given to the works referred to in the notice (Registered No. 90), dated 4th June, 1890, of the London Electric Supply Corporation, on condition that in the streets where the St. James and Pall Mall Electric Lighting Company has already laid mains, the trunk mains referred to in the notice be laid beneath them; that the mains be protected from external injury by a sufficient outer covering, to the satisfaction of the council's engineer; and that the company do give three days' notice to him before commencing the works in any of the thoroughfares referred to in the notice.'"

A further notice (No. 91) of the same company to lay trunk mains in a part of Snow Fields, Bermondsey, was conditionally sanctioned.

The committee also reported:—"The company has given a further notice (Registered No. 92), dated 11th June, 1890, with one plan, of its intention to lay trunk mains in Newcomen Street, Union Street, Charlotte Street, Blackfriars Road and Cross Street; and the company asks that this may be substituted for the notice (Registered No. 61), dated 18th April, 1890, with reference to trunk mains across Borough High Street and Blackfriars Road, and through Southwark Street and Stamford Street, to which the council gave its sanction on 6th May last, at the same time requiring that the mains in Southwark Street should be laid in the subway there. It does not appear to your committee desirable that the council should interfere with the discretion of the company as to the route to be adopted for its trunk mains; but they are of opinion that the company may reasonably be required to lay its distributing mains at the same time as the trunk mains, in order to avoid a second interference with the same streets. Your committee, having given careful consideration to the matter, recommend—'That the sanction of the council be given to the works referred to in the notice (Registered No. 92) of the London Electric Supply Corporation, dated 11th June, 1890, on condition that the distributing mains be laid at the same time as the trunk mains in order to avoid a second interference with the same streets, and subject also to the same conditions regarding protection of the mains and notice of commencement of works as in the case of the two preceding notices.'"

#### WESTMINSTER ELECTRIC SUPPLY CORPORATION.

The committee's report as to this company was as under:—"The Westminster Electric Supply Corporation has given a notice (Registered No. 94), dated June 9th, 1890, with one plan, of its intention to lay mains in the following streets, viz.:—Park Lane, Hamilton Place, Hereford Gardens, North Row (part of), Green Street, Upper Brook Street, Upper Grosvenor Street, Mount Street, Tilney Street, Great Stanhope Street, Park Street, North and South Audley Streets, Grosvenor Square and Street, George Street (Oxford Street), Hart Street, Duke Street, Robert Street, Brook Street, Oxford Street (part of), South Molton Lane (part of), Hertford Street, Brick Street, Piccadilly, Hyde Park Corner, Down Street, Curzon Street, Chapel Street West, Queen Street, Carlos Street, Union Street (part of), Bolton Street and Row, Clarges Street (part of), Half Moon Street, Stratton Street, Berkeley Square and Street, Davies Street, Hay Hill, Bruton Street, Dover Street, Grafton Street, Arlington Street, Park Place, St. James's Street, Bennett Street, Albemarle Street, Old and New Bond Streets, Tenterden Street, Hanover Square and Street, George Street (Hanover Square), Maddox Street, Conduit Street, Prince's Street, Harewood Place, Swallow Place, Hill

Street and Stafford Street. These works are similar to those of the same company which have already been sanctioned by the council; and your committee recommend—"That the sanction of the council be given to the works referred to in the notice (Registered No. 94), dated June 9th, 1890, of the Westminster Electric Supply Corporation, on condition that the company do give three days' notice to the council's engineer before commencing the works in any thoroughfare; that the mains be laid under the footways wherever it is found practicable to do so; that the York stone covering for culverts under 20 inches wide be not less than 2 inches thick, and for wider culverts 2½ inches; and that where it is found necessary to lay the culverts under the carriage ways there shall be not less than 9 inches of Portland cement concrete between the cover stones of the culverts and the under side of the paving."

This recommendation was also approved, as were two others, sanctioning the laying of mains in Kensington Park Road, Victoria Gardens, Ladbroke Grove, and Horbury Crescent by the Notting Hill Electric Lighting Company; and in Brompton Road (part of), Ovington Square, and across Fulham Road by the Chelsea Electricity Supply Company.

#### THE SUBWAYS AND OVERHEAD WIRES BILL.

Mr. Charles Harrison, the Chairman of the Parliamentary Committee, submitted a long report respecting the London Subways and Overhead Wires Bill, and after some remarks as to the preamble and the opposition to the Bill when in committee, proceeded as follows:—"The Committee of the House decided to adopt the scheme of the report of 1885, and, in consequence, has conferred on all the local authorities, including the Commissioners of Sewers of the City of London, the duty of administering in their respective districts the bye-laws to be framed by the council. The Bill, as amended, provides that the council may, from time to time, make and vary bye-laws and regulations with respect to any of the following matters—The position and manner in which wires shall be placed in subways; the manner in which any repairs or alterations in any such wires may be made; the control and regulation of persons resorting to any such subway, and all persons fixing or altering any wire therein; the preparation, deposit, and correction of particulars of wires; the identification of overhead wires by registration or otherwise; the regulation of wires; the strength of the materials to be employed in placing, maintaining, and supporting wires; and the removal of wires erected or placed otherwise than in accordance with such bye-laws and of disused wires. These bye-laws are to be enforced by the local authority, except in so far as they may relate to any subway of the council, in which case they are to be enforced and administered by the council. Power is also given to the council (by obtaining an order of the Board of Trade) to enforce the bye-laws, in case of inadequate enforcement of them, or want of uniformity in the method of administering them, by the local authorities."

#### ELECTRIC LIGHTING ORDERS.

The committee further reported:—"It has been intimated by the Board of Trade that the following electric lighting orders will not be proceeded with:—Metropolitan Electric Supply Company, Limited (City of London); London Electric Supply Corporation Electric Lighting (City) Order; Fulham and Hammer-smith (House-to-House) Electric Supply Order; Paddington Electric Supply Order."

"On the 3rd instant we were authorised by the Council to present a petition against any electric lighting order in any confirming Bill which does not in effect comply with the council's resolutions of the 28th January and 22nd April, 1890. The solicitor has drawn our attention to the Electric Lighting Provisional Order Confirmation Bill, No. 9, which contains the five following provisional orders:—Lambeth Electric Supply Order; North London Electric Supply Order; St. James's Electric Lighting Order; London Electric Supply Corporation Electric Lighting (Metropolitan) Order; and Wandsworth District Electric Supply Order. We are advised that it is unnecessary to present a petition against any of these orders in the House of Commons, and we propose to reserve opposition, should it become necessary, for the House of Lords."

### GENERATION, DISTRIBUTION AND MEASUREMENT OF ELECTRICITY FOR LIGHT AND POWER, APPLIANCES THEREFOR, AND PARTICULARS OF CANADIAN INSTALLATIONS.\*

By A. J. LAWSON, M. Can. Soc. C.E., A.I.E.E., A.M.A.I.E.E.

Concluded from Vol. 26, p. 736.

#### The Royal Electric Company's Dynamo.

Sometimes the machines of the Royal Electric Company for A. C. work are made with the exciter on the same shaft, but more frequently the exciter is separate. In the 1,200-light dynamo with separate exciter, the active iron in the fields weighs about

\* Abstract of paper read May 8th, 1890, before the Canadian Society of the Civil Engineers.

3,400 lbs., and the iron rings of the armature (which is a hollow cylinder built up of laminated wrought iron) weigh 1,250 lbs. The radial depth of these rings is 5-inch. When turned up ready for winding the armature is 24½-inch diameter and 18½-inch long. The diameter when wound is 25½-inch over the bands, and, as the internal diameter of the field bobbins is 25½-inch, there is a clearance of full ⅜-inch all round. The fields are wound with 845 lbs. of No. 8 B. & S. gauge wire; the armature winding consists of 32 lbs. of No. 11 B. and S. gauge wire. The speed of the machine is 1,200 revolutions per minute, and the exciting current at full load is 24 ampères and 90 volts—say, 2,160 watts, or nearly 3 E.H.P. The standard output of the machine is 70 ampères and 1,020 volts, or 7·5 watts per lb. gross weight: 81·41 watts per lb. of the total copper wire, and 2,231 watts per lb. of the wire on the armature.

#### RATE OF ALTERNATION OR PERIODICITY.

In the Brush dynamo the periodicity is 110, while in the Fort Wayne, Westinghouse and Thomson-Houston machines the periodicity is from 125 to 136.

The European practice as to the rate shows considerable variation. Messrs. Ganz & Co., of Buda Pesth, in the Zipernowsky system use 42 cycles; Mr. Ferranti uses 68; Lowrie-Parker work their machines at 80, and Mr. Mordey runs his at 100.

#### CONVERTERS.

##### Westinghouse Converter.

The Westinghouse converter is of the shell type. In the 40-light converter, the core is built up of plates 0·17-inch thick, of which the total weight is 81 lbs. The primary winding of No. 16 wire weighs 10½ lbs., and the secondary wire is No. 3 gauge, 13½ lbs. in weight. At 50 volts and 40 ampères this converter gives an output of 19·09 watts per lb. of active material. The P.D. required between primary terminals is 1,000 volts, developing an E.M.F. of 50 volts at the terminals of the secondary coil.

Recent tests by Dr. Louis Duncan, of John Hopkins University, show 95 per cent. efficiency in a 40-light converter at full load, and only 84 watts loss with no load, and 90, 87·6, 83·3, and 70·7 per cent. efficiency in a 20-light converter at full, three-quarter, half and quarter loads respectively.

##### Brush Converter.

The Brush converters are of the core pattern, with the exception of the two of smallest size. The iron wire in the core of the 50-light converter weighs 92 lbs., the primary wire weighs 20 lbs., and the secondary winding 11 lbs. At 100 volts and 30 ampères its output is thus 24·39 watts per lb. of active material. The case weighs 100 lbs. The 75-light converter core of iron wire weighs 115 lbs., primary winding of copper wire 21 lbs., and secondary winding 15 lbs. At 100 volts and 45 ampères the output is 29·8 watts per lb. of active material. The case weighs 110 lbs. These converters are made in standard sizes of 5, 10, 20, 30, 40, 50, 75, 125, 250 lights, and up to 1,000 lights capacity. They are also made for primary circuits of 1,000 volts pressure, with a ratio of conversion of 10 to 1 or 20 to 1. The core consists of the finest Swedish iron wire, insulated by cotton winding or braiding wound into an octagon form, by having pieces of wood placed under and through the coils, as shown. The secondary wires are then wound over the sections between the wood blocks with insulated pads between them and the iron wire at the corners. Over the corners of the secondary winding are placed other insulating pads, over which are then wound the fine primary wires. There is thus an air space for insulation all round the different coils, except at the corners where the wires lie on the insulating pads. The efficiency of a 75-light converter varies from 98 per cent., with 75 lights attached, to 93 per cent., with 38 lights.

#### THOMSON CONVERTER.

The Thomson converter, manufactured by the Royal Electric Company in this city, is similar in construction to the Westinghouse. The following are the particulars of the 30-light size:—Iron discs, 108 lbs.; primary wire, 920 feet No. 18 B. & S. gauge, 4½ lbs.; secondary wire, 44 feet No. 8 B. & S. gauge, two in parallel, 4 lbs.; total active material, 116½ lbs., with an output of 13·20 watts per lb.; case, 59½ lbs.; weight complete, 176 lbs.

#### METERS.

##### Edison Meter.

In the Edison system of distribution an electrolytic meter has been employed. A disadvantage connected with its use is that nobody except an employé of the company can find out what the meter has registered, and even he has to take every precaution in the washing and drying of the electrodes, and in their accurate weighing in a chemical balance. This meter has been very extensively used, and has evidently given fair satisfaction, but statements from some of the superintendents of Edison stations show satisfaction is not general.

Sir D. Salomons, in the last edition of his work on electric lighting, describes the Edison meter as a thing of the past.

It is but fair to the Edison Company to say that they do not recommend their meters being used in stations of less than 1,000 lights capacity.

##### Aron Meter.

The Aron three-wire meter is used in all the large Edison stations, and by some other companies in Germany. It is a most admirable and reliable instrument, and it is one from which the

consumer himself can learn what he is using. The registering apparatus consists of two sets of clockwork, which will run 40 days with one winding, but which it is intended to wind up every 30 days, when the readings are taken. The pendulum on the left is an ordinary pendulum, uninfluenced by the current; but that on the right consists of a coil of very fine wire, which is connected direct to both the positive and negative wires of the system, while one of the main wires, either the positive or negative, forms a solenoid through which the main current passes, enveloping the fine wire pendulum core.

Before any current is passed through the meter, it should be tested in place to see that the pendulums swing synchronously. If they do not, the indications of one pendulum will gain upon those of the other. The exact adjustment to perfect synchronism is obtained by raising or lowering the weight on the left hand pendulum. If found correct the current is passed through the meter, and the right hand pendulum's movement being accelerated by the action of the current, causes the registering gear to work.

The chief obstacle in the way of the more general employment of this meter is its comparatively high first cost, but it appears to be well worth the money.

#### Shallenberger Meter.

The Shallenberger meter is the one which has been most extensively used in America for the measurement of alternating currents, having been exclusively used in the Westinghouse stations, and being now largely used in those of other companies. About 12,000 are now in use. It is simply a small alternating current motor with registering gearing, and attached vanes placed on the shaft to retard the movement to a degree necessary for adjustment and regulation. Its chief disadvantage is that it does not work readily with a small current, but as this tells against the company and not against the consumer, the latter will probably not have any objection to it.

#### STORAGE BATTERIES.

Storage batteries have not been applied on this continent to any such extent as they have been in Europe. Wherever they are employed, except for propulsion of about a dozen street railway cars, perhaps fewer, it has been for the purpose of securing light after engines and dynamos have been stopped at night, and for railway car lighting. For the latter purpose they have not hitherto been a success, and have been discontinued on the Pennsylvania Road, on the Canadian Atlantic, and on the Grand Trunk Railways, the Julien battery having been used in these cases. On the Intercolonial Railway a great number of cars have been fitted up with these batteries, and it is said several additional charging stations are to be erected, it having been found that the two at present in operation, one at Levis and the other at Moncton, together with such current as may be obtained at Halifax, N.S., and Montreal, have been insufficient, or otherwise expressed, the capacity of the batteries supplied has not been enough to last during the runs between the various stations. The fact that the coal oil lamps, which were wisely left in position, are used on nearly every trip, proves the inadequateness of the batteries which have been supplied for this work.

Outside of these plants storage batteries have been used in five or six places in Canada, among which may be mentioned McGill College, the lights which we have here being run from a Gibson battery in the basement. The battery is charged from a small shunt wound dynamo, driven by an Otto gas engine made by Crossley Bros., of Manchester.

#### VALLEYFIELD AND BARRIE CENTRAL STATIONS.

Let us describe briefly and compare these central stations, both constructed by the writer, and good samples of their respective classes. Both have water power, but the first is on the Edison three wire system, and the second is a Brush A. C. plant. In Valleyfield the power is in the heart of the town and in the centre of distribution, so that it is in the most favourable position for economical distribution by low tension, and the wire used is as small in area as consistent with even voltage at the lamps and best efficiency of the plant. Both stations were built with rooms for the man in charge over the dynamo room. The running expenses are the same or about the same in both places. Probably no other stations of similar capacity in the world cost less to run, the total annual expense in each being less than \$1,600. The capacity of both stations is about the same, say 60,000 watts. The Valleyfield station complete cost \$40,000, including building, water-wheels and flume. The Barrie station, with the same items, cost less than \$22,000, including over \$3,000 for the wire leading into town from the station, five miles distant. In the Barrie plant heavily insulated wire is used throughout the 24 miles of street wiring, and rubber covered wire in all buildings, whereas bare wire is used at Valleyfield for street wiring, and fire and weatherproof wire for inside work. House wiring in Valleyfield is all cleat work; most of that at Barrie is concealed, the lights in the latter place being principally in private houses, and placed on brass fixtures, whilst at Valleyfield drop cords are used exclusively. The pressure in the houses in Valleyfield is generally 220 volts, the three wires being carried in in all cases where this system is used, in order to maintain as even a load as possible on both sides of the circuit. In Barrie the pressure is 93 volts on the lamps in the houses, and nothing higher than 98 volts can ever enter them. The charge for current averages at Valleyfield \$9 per light a year, and at Barrie \$7.50. This means that, making due allowance for all contingencies in both cases, the Barrie plant will pay its shareholders better than the Valley-

field plant will, while the customers pay \$1.50 per light a year less. In the Barrie station Westinghouse meters are used on the premises of the largest consumers, and these can be read by the consumer as well as the meter man, the cost of operating the station is not increased, the man who attends to the wiring of the buildings in town and to collection of accounts taking the readings; while, if the Edison meter be used at Valleyfield, another man will require to be employed to attend to the meters solely, and his wages will have to be added to the operating expense and thus reduce the net revenue.

The respective sizes of wire used in both stations is worthy of study. At Barrie the loss in the feeder is 14½ per cent. at full load, nearly the same as at Valleyfield. The length of feeder at Barrie is 10 miles for the complete circuit, and the size of wire No. 4 B.W.G. At Valleyfield the feeders are three in number and three in a set; the longest is less than two miles for the complete circuit, and the size of the outside wires No. 000 B.W.G. The No. 4 wire used at Barrie weighs 985 lbs. per mile, including insulation, and the No. 000 bare wire at Valleyfield weighs 2,886 lbs. per mile.

It may be and has been said that in the one case you have a perfectly safe low tension system, while in the other, to use the pet phrase of the paid advocate of low tension, the New York State electric executioner, you have the "deadly alternating current." That is admirable as a trade trick, but even the Edison Company now advertise that they are prepared to supply A. C. plant to all who desire it. Either there is less danger in the A. C. system than they would have the public believe, or they are ready to subordinate principle to pocket in the contest. To alter slightly a phrase from Dickens's "Holiday Romance," the Edison people have been advising the public to "prohibit the use of the alternating current system on the ground of humanity, as it makes ours too expensive." In an article on the subject, Sir William Thomson, the greatest living authority on electrical matters, says:—

*"In passing, I may remark that 100 volts in the house is perfectly safe to the user, whether the current be alternating or continuous, as is proved by large and varied experience in England."*

It must be freely admitted that the accidents reported from New York were real and not invented for sensational purposes, but it must also be acknowledged that in no other city in the world is there such an organisation as the Board of Electrical Control, to which appointments are made by political influence only, regardless of qualification, and one of whose advisers is, or was, an individual whose business it was for the past two years to discredit the alternating system, for which service he was well paid. In no other city in the States or Canada is there such bad construction of overhead conductors as there was in New York, and the underground construction there is nearly as dangerous on account of existing grounds on the wires and leakage of current, and the consequent liability to cause explosions of gas in subways, as has already been repeatedly done, besides turning the paving stones into "a molten mass."

Furthermore, the insulation of the overhead wires, which have been in use in some cases over eight years, had rotted off, being of the quality known as "Underwriters," or "Undertakers," if you will.

Four deaths have occurred in the whole history of electric lighting in Canada from shocks of electricity, and two of these were the result of bad insulation of wires and faulty construction by a purchasing company doing its own work, without employing anybody having any knowledge of the business, in order to cheapen the first cost of the plant, and which purchased a job lot of poorly insulated wire, and ran two dynamos in series with 100 arc lamps in circuit at a tension of nearly 5,000 volts. The current used on that system was a continuous one, not a pulsating high tension current, as stated in a circular which some of you may have received.

Reverting to our main subject. Thirty wires radiate from the Valley field station; one pair carry the current from the Barrie station. In the Barrie station the pressure of primary current is the highest which has yet been used in this country, being about 2,100 volts average on the feeder. This pressure is raised or lowered by increasing or decreasing the exciting current according to the load shown on the central station ammeter, which is graduated to single amperes, and is indicated by a Cardew voltmeter, which, as elsewhere mentioned, is attached through a converter to the armature. Instead of having a compensator, as is used in the Westinghouse system, a table of loads and the corresponding pressures to be carried at the station is used. This method, though of course not absolutely perfect, owing to the rise of current with increase of voltage and *vice versa*, answers very well. The Cardew voltmeter in the company's office in town, which is an excellent check upon the dynamo attendant's work, shows an average variation of two volts only in a night's run. The mains in town, which aggregate nearly 14 miles in length, are calculated for a loss of only 2 per cent. at full load, which gives a difference of two-thirds of a volt per lamp up or down from the standard. The house wires, which are insulated with rubber and tape, are calculated for 1 per cent. loss only at full load. As most of the lights are taken in private residences, where the whole number are hardly if ever in use at one time, the loss of light through resistance of the house wiring is practically nil.

#### MEASURING INSTRUMENTS.

The Ayrton and Perry instruments have been used to a very considerable extent in this country, and until recently were the most accurate of all really portable electrical measuring instru-

ments. There is a sample on the table before you. They are only suited for direct currents, and are open to the objection that they have considerable friction and a high temperature error if kept in circuit, which they should never be except only for a few seconds when taking readings.

The Weston voltmeter has the great advantage of extreme accuracy and very high resistance, averaging about 20,000 ohms, so that the quantity of current passing is extremely small. They may be kept continuously in circuit without any material variation in their readings. They require careful handling, of course, as do all electrical instruments, but they are the most accurate and reliable of all portable testing instruments for continuous currents. The voltmeters contain a calibrating coil by which their constancy can be at all times tested. The writer has used quite a number of these instruments, which he has checked with each other, and has sometimes compared the higher and lower scale by taking the P.D. difference between terminals of single cells of secondary batteries, and then, putting the whole of the cells in series, compared the reading of total E.M.F. of the battery. Several tests of this nature have come out within one quarter of a volt. The calibrations are in single volts on the higher scale, and thirtieths, twentieths, or tenths of volts on the lower scale. The ammeters read to tenths of amperes in the small sizes. In both the divisions of the scale are so wide that one-quarter of these values can be read with perfect ease.

For the most perfect readings by these instruments they should be set quite level, and five feet away from any other instrument, or from any mass of iron or steel, and so placed that the index will point due west when at the centre of the scale, but these precautions are not necessary for ordinary testing of pressure in buildings, as the error can seldom be more than half volt if otherwise placed.

The Cardew voltmeter is used for both direct and alternating currents, and is made to be used either vertically or horizontally.

The horizontal pattern has the advantage of being steadier than the vertical instrument, owing to the disturbance caused by currents of air passing up the tube of the latter. All the more recent forms of this instrument have an adjusting screw outside of the case to bring the needle to zero, which should be done before the current is turned on. No adjustment should be made while the wire remains warm, as the section of the wire may be altered by any tension put upon it while in this condition and the calibration destroyed.

For alternating and direct currents Sir Wm. Thomson's latest instruments are the finest yet produced, but are more suited for standard or station use than as testing instruments. In the electrostatic instruments no current passes through the instrument at all, and so the conditions of a battery or dynamo on open circuit can be found with perfect accuracy. The electrical balances are adapted for both alternating and direct currents. To anybody desiring a fine standard laboratory or station set of large range, none are better than these instruments, expensive though they be. All stations for alternating current work should have a Cardew or Thomson voltmeter, a portable Thomson multicellular electrostatic voltmeter for testing pressure in consumer's premises, &c., and a Thomson ampere gauge. For direct current stations Weston or Cardew voltmeters for station work and line testing should be used, and Thomson ampere gauges for current measurement.

#### TRANSMISSION OF POWER.

In his address at the annual meeting, the President touched upon the subject of electrical transmission of power, mentioning the installation at the Chollar Mine, Virginia City, Nevada. There a Brush plant is used, as then stated, placed 1,680 feet below the surface of the ground, in a chamber 50 feet long by 25 feet wide by 12 feet high, hewn out of solid porphyry. The small stream of water, which drove the wheels at the surface of the mine, was carried down through two iron pipes, one 10-inch and the other 8-inch diameter, connected together at the bottom of the shaft by a Y into a single pipe 14-inch diameter, from which 6-inch pipes lead to the Pelton water wheels' nozzles, and there develops sufficient energy through the generators to transmit to the surface by well insulated cables 450 H.P. The waste water is conveyed away through the Sutro Tunnel, pierced through the side of the mountain for the drainage of the mines—in itself a monument of engineering ability and Western enterprise. This is at present the largest installation in the world for transmission of power by stationary electric generators and motors.

About August last a generator and a motor of exactly the same type as those placed in the Chollar Mine were installed at Messrs. Barber & Co.'s Mills, Georgetown, Ont. The water of the Credit river was dammed over two miles below the mill, and a water wheel and shaft were placed in a building there along with the generator. A copper wire was carried back and attached to the motor, which develops 75 H.P. in the mill.

#### ELECTRIC RAILWAYS.

Four years ago there may be said to have been no electric railways in operation in America. Yet, according to the most reliable sources of information there were 636½ miles of electrically equipped railways in operation, and 700 miles under construction at the end of December, 1889; 1,063 electric cars were then running, and 771 cars were being equipped. The total number of completed roads was 107, and 85 were under construction. Of these roads two were running in Canada, their total length being 10 miles, and these were equipped with 10 motor cars. The first, at Windsor, Ont., with two miles of road and two cars,

has now been at least four years in operation; the other is at St. Catharines, and the length of road is eight miles, and it is equipped with eight cars. Both roads use the Vandepoele system. The road at Victoria, B.C., is now running. The track is four miles long, with six motor cars. The Vancouver road, which is likewise four miles in length, and will be equipped with four motor cars, will be running about the beginning of June. The Thomson-Houston system is used in both cities, and a contract for a short line in Toronto, on which two motor cars will be used, has lately been closed with the Thomson-Houston Company, which has done by far the largest amount of work in electric railways, the Sprague Company ranking next. The table given below shows the amount of work done by various companies and that under construction in January last.

#### ELECTRIC RAILWAYS.

*In operation and under construction, January, 1890.*

Name of System.	In operation.		Under construction.	
	No. of Roads.	No. of Cars.	No. of Roads.	No. of Cars.
1. Thomson-Houston ...	47	490	37	509
2. Sprague ... ..	35	408	33	218
3. Daft ... ..	10	66	5	15
4. Van de Poele ... ..	8	57		
5. Short ... ..	3	17	1	5
6. Bentley-Knight ... ..	1	6	1	20
7. National Electric Traction Company ...	1	1	5	not given
8. Julien ... ..	1	10		
9. Fisher ... ..	1	4	2	not given
10. Henry ... ..	1	4		
11. Rae ... ..			1	4

Within the past few months great activity has obtained in electric railways in the United States, and the two leading companies in this business have contracted for several hundreds of cars each; the lead of the Thomson-Houston Company having increased, while the Sprague Company has over 1,200 motors cars in operation or in course of construction.

The largest electric street railway system in the world is that of the West End Railway of Boston, contracted for by the Thomson-Houston Company, of which the following particulars may be of interest:—At the present time there are 150 cars running, and when completed there will be 600 in operation. Now there are 56 miles of road electrically operated, and 236 are to be equipped. In the power station from 3.30 till 7 p.m. the electrical plant, which is capable of developing, if called upon, 2,500 H.P., usually furnishes from 1,000 to 1,500 H.P. The cars generally in use are 16 feet closed cars, each carrying 30 passengers and towing a similarly loaded car. Such a car, equipped with a single 15 H.P. motor, averages in speed 15 miles an hour on the level, and will pass a grade of 5½ per cent. at the rate of nine miles an hour. Such work is, however, rather severe for constant use, and for heavy work they are using two 15 H.P. motors. The potential used is 500 volts, and the average rate of speed is from 10 to 15 miles an hour. The weight of a motor car equipped is 6 tons. The cost of steam power is from one to four cents. per car mile, taking 100 miles per car per day as a basis; the cost of operation and maintenance, four to 6 cents per car mile on the same basis; the cost of repairs to electrical apparatus is from one and a half to two cents per car mile; cost of management from one to two cents per car mile, and the average total cost of operation is nine and a half to sixteen cents per car mile, according to the number of miles operated.

Unfortunately the severe winters and heavy snowfalls of Montreal and other cities in Eastern Canada preclude the possibility of working electric railways the whole year on our present street roads, but it is a question worthy of the study of members of this society, whether or no it would pay to operate our roads electrically during the seven months of open weather which we get, or if a system of overhead railways along our main traffic thoroughfares operated electrically, and which could be run the whole year round, would not be a good investment.

#### STREET WIRING FOR ELECTRIC LIGHTING.

First, on account of the dangers of breakdown from heavy sleet storms, and the variation in tension of wire caused by the extremes of temperature experienced in Canada, poles should be placed not more than 135 feet apart, or, say, 40 to the mile. They should all be good, sound, straight cedar, 7 inches diameter at the top end and not less than 35 feet long, and should be set in the ground to a minimum depth of 6 feet and securely tamped. The cross arms should be of sound timber, 4½-inch by 3½-inch, well painted and fixed in gains cut in the poles, and secured thereto by lag screws 8 inches long, which would thus enter into the pole about 4½ inches. They should never be attached by spikes only. Wherever telephone or telegraph wires run in the same streets, the poles should be of sufficient height to carry the electric light wires at least 4 feet above them. Bare wire for carrying either high or low tension currents in town should be strictly prohibited. The insulation of the wire should be both fire-proof and weather-proof, and be of such tough texture as to withstand

abrasion should other wires by any means fall across the electric light wires. None but the best double-petticoat glass insulators should be used.

For outside construction some of the English Board of Trade regulations, which might be adopted with advantage in this country are as follows, the numbers given being those of the regulations:—

1. An aerial conductor in any street shall not in any part thereof be at a less height from the ground than 20 feet, or when it crosses a street, 30 feet, or within 6 feet of any building for the purposes of supply.

2. Every support of aerial conductors shall be of durable material, and properly stayed against forces due to wind pressure, change of direction of the conductors, or unequal lengths of span, and the conductors and suspending wires (if any) must be securely attached to insulators fixed to the supports. The factor of safety shall be at least 6, and for all other parts of the structure at least 12, taking the maximum possible wind pressure at 50 lbs. per square foot.

5. Every aerial conductor shall be protected by efficient lighting protectors.

6. Where any conductor crosses a street, the angle between such conductor and the direction of the street at the place of such crossing shall not be less than 60°, and the span shall be as short as possible.

7. Where any aerial conductor is erected so as to cross any other aerial conductor, or any suspended wire used, for purposes other than the supply of energy, precautions shall be taken by the owners of such crossing conductors against the possibility of that conductor coming into contact with the other conductors or wire, or of such other conductor or wire coming into contact with such crossing conductor by breakage or otherwise.

11. The insulation resistance of any circuit using high pressure aerial conductors, including all devices for producing, consuming or measuring energy connected to such circuit, shall be such that should any part of the circuit be put to earth the leakage current shall not exceed  $\frac{1}{25}$ th of an ampere in the case of alternating currents. Every such circuit containing high pressure conductors shall be fitted with an indicating device which shall continuously indicate if the insulation resistance of either conductor fall below the conditions required by this regulation.

14. The owner of every aerial conductor shall be responsible for the efficiency of every support to which such conductor is attached.

15. Every aerial conductor, including its supports, and all the structural parts and electrical appliances and devices belonging to or connected with such conductors, shall be duly and efficiently supervised and maintained by and on behalf of the owners as regards both electrical and mechanical condition.

16. An aerial conductor shall not be permitted to remain erected after it has ceased to be used for the supply of energy unless the owners of such conductor intend, within a reasonable time, again to take it into use.

17. Every aerial conductor shall be placed and used with due regard to electric lines and works from time to time used, or intended to be used, for the purpose of telegraphic communication, or the currents in such electric lines and works, and every reasonable means shall be employed in the placing and use of aerial conductors to prevent injurious affection, whether by induction or otherwise, to any such electric lines or works, or the currents therein.

The author considers that rules 7, 13, 14, 15, 16 and 17 should be equally binding upon telegraph and telephone companies whose wires are often as carelessly constructed as those of any electric light company, and have in consequence been quite as blame-worthy for fires originating from electric currents.

#### HOUSE WIRING.

In the interior wiring none but high class rubber insulated wire, protected by an outer linen tape or other efficient covering, should be used.

None but porcelain or slate base cutouts and switches should be allowed, and the sweating of drop wires for single lights on the main wires (such wires being afterwards twisted together and brought down to the lamp socket) should be prohibited.

Wherever lights are suspended by wires, stranded conductors, equal in area to No. 20 standard wire gauge, covered with a good solid rubber coating and protected on the outside by silk or cotton braiding, should be used, and where taken off from the main wires a porcelain rosette cut-out, such as the K.W. rosette, should in all cases be provided, or a wood base rosette may be used, provided it is rendered fireproof.

No switches should be used which do not break contact quickly and automatically, or in which spring copper makes a connection; such copper is heated by the passage of a large current, and, by losing its hardness therefrom often fails to make good connection, and so may cause an arc to form. The Paiste switch is the only one at present made on this continent in which these objections are successfully met.

Fuses for cut-outs should not be interchangeable with others of widely different capacity. Over-loading of wires first designed for lighter loads would then be impossible.

The joints in wires are preferably made with connectors such as the MacIntyre wire joint, as soldered joints on which acid has been used frequently corrode through the excess of acid not having been removed on completion of the soldering, and it has been the author's experience that ordinarily wiremen will not

take the time or trouble to make a good joint with rosin as a flux.

It must be remembered that a low tension continuous current is more liable to cause a fire in case of short circuit between the main wires than an alternating current, owing to the connection which exists directly between the dynamo and the house wires, permitting the entrance into the house of an enormous current, while with the alternating current system the short circuiting of the secondary house wires will only result in the immediate melting of the fine wire fuse in the primary circuit of the converter. There should be no relaxation, therefore, of adopted regulations in favour of low tension direct systems on account of supposed greater safety, a thing which does not exist in their case, but both direct and alternating current systems should be treated alike so far as the wiring of consumers' premises is concerned, and the present standard should be raised, not lowered.

It should not be forgotten that one of the most important elements in the attainment of perfect safety to everybody concerned is the employment by supply companies of properly qualified and experienced labour both for the construction and for the running of plants. It will be found to be very poor economy to employ bell-hangers, plumbers and even shoemakers on work requiring considerable electrical and mechanical knowledge and clear judgment, as is done at the present time in some Canadian stations which might be mentioned, merely for the sake of saving two or three hundred dollars a year in wages, a sum which is much more than counterbalanced by the unsatisfactory results in the lighting and the additional cost of repairs. Nor should it be forgotten that a cheap and poorly constructed electric lighting plant is the worst of all possible investments.

## PROCEEDINGS OF SOCIETIES.

### Physical Society.—June 20th, 1890.

Prof. W. E. AYRTON, F.R.S., President, in the chair.

Mr. C. V. BOYS read a paper on "The Measurement of Electro-Magnetic Radiation," by himself, Messrs. A. E. Briscoe and W. Watson. When Mr. Gregory described his new electric radiation meter on November 1st, 1889, one of the authors said that the observed effects might be due to some cause other than expansion by heating, and that if it was a true heating effect it might be measured thermally. The present communication describes experiments undertaken to investigate the question. The first method employed was developed from the idea that if two fine wires be placed near together and both act as resonators to a primary oscillator, the electro-dynamic attraction caused by the electric currents up and down the wires and the electrostatic repulsion between the charges on them might result in the relative motion of the two wires. From theoretical considerations based on the assumptions that the currents are harmonic in time and space, the authors inferred that the electro-dynamic effect would preponderate at the middle of the wires, whilst the electrostatic repulsion would be greatest at the ends. To cause the attractions and repulsions to conspire, cranked resonators were made; one was fixed and the other suspended by a quartz fibre, to turn about a middle line. These were enclosed in a glass vessel and on starting the oscillator a turning movement was observed, in a direction opposite to that expected. This motion was eventually traced to the electrostatic influence of the oscillator for although the imperfectly conducting surface of the glass acted as a perfect screen from such action when the potentials of the oscillator were varied slowly, it did not do so for changes occurring about 500 million times per second. After adopting means to avoid this disturbance and constructing lighter resonators the experiments were repeated with negative results. From the dimensions of the quartz fibre used it was estimated that a force of 158 millionths of a grain could have been detected with certainty; this would have corresponded to about  $\frac{1}{300}$ th of an ampere in each resonator. It is hoped that by further increasing the sensitiveness of the apparatus and using parabolic reflectors the effect sought for may be detected.

In the second method of attacking the subject, a Joule's dynamometer was employed. This consisted of a glass tube with a partition along the middle extending nearly to the ends. If one side of the tube be warmed, convection currents circulate and deflect an index placed in the stream. A small mirror suspended about one edge and counterpoised, was used for an index and was so sensitive that it was impossible to get the air still enough by any ordinary method of screening. However, by the ingenious device of putting the thermometer within a larger tube kept rotating by clockwork, the difficulties were surmounted. A doubled wire, placed in one side of the thermometer, served as resonator, and on starting the oscillator a large deflection resulted. A similar deflection was caused by applying about one-third of a volt to the ends of the wire. This proved that the effect observed by Mr. Gregory is due to heating. The least rate of heating observable with the air thermometer was found to correspond to one calorie (gramme-water-centigrade) per 24 hours in the whole tube, or one calorie per centimetre of wire in 103 days.

Dr. LODGE asked Sir William Thomson whether, when electric pulses travel along parallel wires with the velocity of light, any

action could exist between them, for two charged spheres travelling together at that velocity exert no mutual attraction or repulsion.

In reply, Sir WILLIAM said he was inclined to think Mr. Boys's treatment of the subject was in the main correct, but it was quite possible that at such velocities the ordinary laws might be modified by the fact that the time taken for the force to be propagated from wire to wire is comparable with that required for the pulse to travel the whole length of the wire. As an example of the peculiar effects of rapid discharges, he said he had seen two copper wires which had been flattened against each other by lightning.

Mr. Boys thought that in his resonators a condition analogous to stationary waves would exist, for the pulses are reflected from the ends.

Dr. LODGE said he had that afternoon observed the action of parallel strips when Leyden jar discharges were passed through them. The strips gave a kick at each discharge.

Mr. GREGORY mentioned that in trying to increase the sensitiveness of his meter so as to measure the variation with distance, he had found that two resonators in proximity interfered with each other. He had, however, succeeded in increasing the sensibility about five-fold.

Prof. WORTHINGTON asked if it was possible to measure the energy of the oscillator, and also whether the quantity caught by the resonator could be estimated from the solid angle it subtended at the source of energy, wherever that might be.

Prof. PERRY considered it easier to infer the energy of the source from that received by the resonator.

Dr. LODGE said the energy of the source could be easily measured. The power radiated was enormous whilst it lasted, vastly exceeding that of tropical sunshine; if it could be made continuous the apparatus would soon be red hot. The energy radiated, he said, converges on the resonators and hence the solid angle method of estimating the amount received would be erroneous. Moreover, the source was not at the oscillator, but at a quarter wave length from it, and most of the energy returns to the oscillator; only a small fraction is splashed off and sent into space. Small oscillators radiate powerfully because the quarter wave lengths are small, whereas the slow oscillators or alternators used commercially radiate very little of their energy. The exact law of variation of intensity of radiation with distance was rather complicated, but the theory had been completely worked out by Stokes in 1848.

Mr. BLAKESLEY thought the energy that returns to the oscillator would be available for subsequent radiations.

Dr. LODGE pointed out that wires or other resonators placed within the quarter wave length would intercept part of the returning energy.

Two communications, "Notes on Secondary Batteries," by Dr. GLADSTONE and Mr. HIBBERT, and "An Easy Rule for Calculating approximately the Self-induction of a Coil," by Prof. J. PERRY, were taken as read.

In the first of these, the authors show cause for believing that the beneficial effect produced by adding sodium sulphate to the ordinary electrolyte is due to its power to diminish local action between the electrolyte and different parts of the lead plates. As regards the chemical actions which take place during the working of ordinary cells, they see no reason to doubt the view put forward by one of them in 1882, that the substance produced in the voltaic reaction is ordinary lead sulphate  $Pb SO_4$ . They also conclude that the high E.M.F. of a cell immediately after stopping the charging current is due to the inequality of acid strength near the two plates, and the gradual fall of E.M.F. is caused by the equalisation of strength produced by diffusion.

Prof. Perry's rule relates to hollow cylindrical coils, and is expressed by the following formula:—

$$L \text{ (in secohms)} = \frac{n^2 a^2 + 10^7}{1.844a + 3.1c + 3.5b}$$

where

- $n$  = number of windings,
- $a$  = mean radius of winding in centimetres,
- $b$  = axial length,
- $c$  = radial depth of winding,

and  $b$  and  $c$  are less than  $\frac{a}{2}$ .

The time constant of such a coil is given in terms of the volume of copper ( $v$ ) in cubic centimetres by

$$\frac{L}{R} = \frac{v + 1,000}{.728a + 1.33c + 1.5b}$$

and the conditions for making this small are pointed out in the paper.

A paper by the Rev. T. Pelham Dale was postponed till next meeting.

#### Royal Society.

"Contributions to the Molecular Theory of Induced Magnetism." By J. A. EWING, F.R.S., Professor of Engineering in University College, Dundee. (Abstract of paper read June 19th).

After referring to the discussion by Maxwell of Weber's theory, which ascribes the magnetisation of iron and other magnetic metals to the turning towards one direction of molecules which are already permanent magnets, and to suggestions by Profs. Wiedemann and Hughes, and lately by Mr. A. E. Kennelly (the *Electrician*, June 6th and 13th of 1890), the writer describes experiments which he has made bearing directly on the molecular

theory. The experiments have been made by grouping near to one another a large number of small pivotted magnets each free to turn about a fixed centre, and studying the configuration which the group assumes and the manner in which it yields when an external magnetic force is imposed. The results do not support the idea that the molecular magnets form closed chains in unmagnetised iron. They lead, however, to the important conclusion that no arbitrary conditions of directional constraint need be postulated to make the behaviour of the molecular magnets agree with what is known about magnetic quality.

In the writer's view the molecular magnets are perfectly free to turn in response to external magnetic forces, except in so far as they are constrained by the magnetic forces which they mutually exert on one another. This theory is briefly discussed in the paper in relation to the form of the magnetisation curve, to the character of cyclical processes, and to the known effects of temperature, vibration, stress and so forth, and the following conclusions are stated:—

1. That in considering the magnetisation of iron and other magnetic metals to be caused by the turning of permanent molecular magnets, we may look simply to the magnetic forces which the molecular magnets exert on one another as the cause of their directional stability. There is no need to suppose the existence of any quasi-elastic directing force or of any quasi-frictional resistance to rotation.

2. That the intermolecular magnetic forces are sufficient to account for all the general characteristics of the process of magnetisation, including the variations of susceptibility which occur as the magnetising force is increased.

3. That the intermolecular magnetic forces are equally competent to account for the known facts of retentiveness and coercive force, and the characteristics of cyclic magnetic processes.

4. That magnetic hysteresis and the dissipation of energy which hysteresis involves are due to molecular instability resulting from intermolecular magnetic actions, and are not due to anything in the nature of frictional resistance to the rotation of the molecular magnets.

5. That this theory is wide enough to admit explanation of the differences in magnetic quality which are shown by different substances, or by the same substance in different states.

6. That it accounts in a general way for the known effects of vibration, of temperature and of stress, upon magnetic quality.

7. That, in particular, it accounts for the known fact that there is hysteresis in the relation of magnetism to stress.

8. That it further explains why there is, in magnetic metals, hysteresis in physical quality generally with respect to stress, apart from the existence of magnetisation.

9. That, in consequence, any not very small cycle of stress occurring in a magnetic metal involves dissipation of energy.

#### NEW PATENTS—1890.

9263. "Improvements in electric cut-outs and switches or other circuit breakers." J. DRUMMOND. (Communicated by R. O. G. Drummond and D. A. Bremner, South Africa.) Dated June 16.

9274. "Utilising the waste or other water power of rivers, canals, tides, &c., for electrical or other purposes, by constructing or erecting lock, shute, or other weirs with hollow iron piers and foundations or casings upon iron screw or ordinary piles, and filling with concrete, &c., to carry water wheels or encased dynamo water wheels of any kind, or by floating dynamos on such dynamo water wheels." P. H. WILLIAMS. Dated June 16.

9275. "Constructing water wheels of any form, and providing or utilising space in the interior for enclosing or attaching dynamos of any kind, or attaching encased dynamos to water wheels of any kind, or to their spindles or shafts, or floating dynamos." P. H. WILLIAMS. Dated June 16.

9343. "A new and improved flexible-jointed pipe for fluids, gases, &c., and for insulation of electric or other wires." R. M. HAGUE. Dated June 17.

9357. "Improvements in switches for electric glow lamps." A. BARKER. Dated June 17.

9361. "Improvements in electric reduction of metals, and in apparatus therefor." T. L. WILLSON. Dated July 17.

9395. "Improvements in electrical apparatus for the production of rotary motion." O. ROMANZE, of and on behalf of the firm of ROMANZE and WEISE, and F. W. WHITE. Dated June 17.

9602. "Improvements in the distribution of electrical energy." SIEMENS BROTHERS & Co. (Communicated by Siemens and Halske, Germany.) Dated June 20.

9668. "Improvements in elevating and lowering electric lights." J. P. HEBENDAHL, G. MILLER and E. F. WARNER. Dated June 21. (Complete.)

9683. "Improvements in electrically driven percussive tools, and in the means of operating the same." L. B. ATKINSON. Dated June 21.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1889

3424. "Improvements in dynamo-electric machines and motors." J. SWINBURNE. Dated February 26. 8d. Claims:—A generator or motor for direct currents, having: 1. A reversing armature core with the commutator connections embedded in it. 2. A reversing armature with the commutator connections thin where they pass through the reversing field. 3. A reversing armature core with each commutator connection passing over the outside only once, substantially as set forth. 4. Reversing magnets adjustable as to position, substantially as described. A synchronising alternating current motor: 5. In which the current-turns on the field magnets are decreased when the load increases. 6. Excited from its own armature. 7. A self-exciting alternating generator or motor, with two or more exciting coils on the armature giving currents differing in phase, substantially as and for the purposes set forth.

3671. "Improvements in or relating to winding and synchronising clocks by electricity." A. J. BOULT. (A communication from R. J. Pouchard, of Paris.) Dated March 1. 8d. The object of the present invention is to design mechanism by means of which clocks driven by weights can be wound up and synchronised or regulated electrically by passing an electric current every 24 hours over a special wire or an ordinary telegraph line. 7 claims.

4846. "Improvements in electric light fittings and Conductors." C. K. FALKENSTEIN, E. ROUSSEAU, and C. K. FALKENSTEIN. Dated March 20. 6d. Claim:—An insulated conductor for two or more wires, consisting of a core having grooves, in which the wires are laid, and a tube covering the core and wires.

5676. "Improvements in electric bells." D. REID and J. KEAN. Dated April 3. 8d. The inventors employ a relay connected to the battery and bell, and they use the same battery for actuating both the relay and the bell; one terminal of the coil of the relay is connected to one pole of the battery direct, and the other terminal of the coil of the relay is connected to the other pole of the battery through the bell-push, or other contact maker, which may be at a considerable distance from the bell. One pole of the battery is also connected to the armature of the relay, while the other pole of the battery is connected through the circuit of the bell to a stop of the armature. 1 claim.

5768. "Improvements in wooden casings for electrical conductors." W. G. DE FORGES GARLAND. Dated April 4. 6d. Claim:—A wooden casing or protective covering for electrical conductors, adapted for being readily fixed in position without risk of injury to the insulation, substantially as described with reference to the drawings; the same comprising a grooved fixed part and a removable covering piece (or pieces), suitable for being applied laterally to the said fixed part, and for engaging therewith.

7023. "Improvements in electric meters." R. SNOWDON. Dated April 27. 1s. 1d. Relates to that type of electric meters known as "motor meters," and the improvements consist in the construction of the meter in such a manner that the motion of the motor is retarded or resisted by a viscous fluid resistance, and so also that the current or currents passing through the armature of the meter is, or are, exclusively the current or parts of the current to be measured, as and for the purposes described. 12 claims.

7127. "Improvements in or connected with the brush contacts of electric railways." G. E. VAUGHAN. (Communicated from abroad by S. Trott, of Nova Scotia.) Dated April 29. 8d. Has for its objects to more effectually insulate the conductors connected with the contact brushes, to protect them from injury, and to provide an efficient carrier for the conductors and contact brushes. 3 claims.

7198. "Improvements in the manufacture of electric arc carbons." W. E. ADENEY and L. SAUNDERSON. Dated April 30. 4d. Powdered gas coke is mixed with powdered coal in the proportion of coke varying from 80 to 50 per cent., and that of coal varying from 20 to 50 per cent. To this mixture is added 1 to 10 per cent. of infusible or difficultly fusible substances such as—compounds of aluminium, silica, calcium, iron, &c., such as glass, cyanite, kaolin, bauxite, asbestos, pumice, felspar, gadolinite, samarskite, quartz, zircon, limestone, strontianite, dolomite, witherite, phosphate of lime, braunite, titanite, chrome iron ore, wolfram, molybdenite, fluorspar, cerite, cryolite, phosphate of aluminium, magnesite or compounds of nickel and cobalt. After careful mixing the whole is introduced into iron moulds and heated under pressure, at first gently, but finally very strongly. The carbon rod so made, if found too porous, is heated and introduced into hot coal tar, and the whole heated (preferably in vacuo) for some time. It is then taken out, and its surface cleaned, and then introduced into a mould and again heated under pressure. 5 claims.

7428. "Improvements relating to electric accumulators or secondary batteries, and to the manufacture of plates or electrodes therefor." C. POLLAK. Dated May 3. 8d. The plates are prepared by mechanically forming grooves or notches on the two sides of sheets of lead, these sheets being caused to pass between two cylinders covered with wire gauze, or carrying indented discs, or alternately full discs and indented discs, in such a manner that the grooves or notches made on either side of the plates in these rolling motions shall be of a sufficient length and depth to receive and maintain spongy lead. 5 claims.

8459. "Improvements in dynamo-electric machines and electro-motors." T. L. WILLSON. Dated May 21. 11d. Relates to a drum-shaped armature, the conductors of which consist of a single layer of longitudinal bars, with commutating brushes bearing upon these bars at one or both ends in line with the fields of force, to conduct the current to and from each bar during its passage through the magnetic field. The bars are thus cut out of the circuit as soon as they pass beyond the field, and remain with open terminals during their period of inactivity. 7 claims.

20288. "Improvements in conduits for electric conductors and combined conduits and conductors, and in the manufacture of the same." H. B. TATHAM and J. TATHAM. Dated December 17. 8d. The object of this invention is to so construct a conduit for electrical conductors that it will provide an effective insulation for the same, can be manufactured at small cost, and will be practically indestructible under ordinary conditions of use. 5 claims.

## CORRESPONDENCE.

### The Lineff Improved System of Electric Traction.

In your last issue I observe a note stating that a trial of the above took place on Wednesday, last week, and that a notice of the system appeared in the REVIEW of May 9th. I have compared the latter notice with those which were published by your two electrical contemporaries last week, and find that beyond a few details there is no difference, although the description in the REVIEW was given six weeks previously. It is, however, not to this that I wish to draw your particular attention, but to the trial and to the remarkable statements made by one of your contemporaries.

I am informed by one who was present at the trial, that the runs made by the open car extended over a considerable length of track—namely, about 25 yards! This is, indeed, a remarkable distance to make a demonstration of any system of electric traction; and yet, according to one electrical journal, "the trial seemed perfectly successful." Now, I contend, and I think with reason, that the trial was not a demonstration of the system, and that the working capability of the car was not demonstrated. To run a car to and fro 25 yards is purely a laboratory experiment, if such a phrase is admissible, and proves nothing. As far as I remember, in reading of trials of other systems of electric traction, whether third rail, "series," or accumulator, the demonstrations have been made on tracks at least one mile, and sometimes several miles long. I think, therefore, that in the case of the Lineff system a trial should have been made on a moderate length of track, and, until such is done, the system should be ignored.

Then, again, the same contemporary states that it has been informed that the "car has been run at the rate of 30 miles an hour." I should like to know where—possibly on the 25 yards track. The statement is decidedly absurd. There is not, I believe, a single electric car in the United Kingdom which has ever attained that speed. On the Barking line it is claimed that the accumulator cars have been run at 20 miles an hour, a statement which is very doubtful, considering the power of the motors, the heavy and clumsy build of the cars, and the nature of the line. Even in the United States I do not think there are any electric cars which have attained the rate of 30 miles an hour.

I am informed that the members of the Chiswick Local Board who objected to the old open slot system of Mr. Lineff, have expressed themselves as satisfied with the new method. This is interesting, considering the length of track upon which the car was run when those gentlemen were present over a fortnight ago.

There are three points upon which I should like to be enlightened. It has been found that none of the front and rear sections of the surface conducting rails are charged when the car is over any two charged sections. How will this be in rainy weather, what will be the effect when snow is on the ground, and how will the snow be removed? Moreover, the Press view last week was, I am told, arranged in an unsatisfactory manner.

F. Baines.

## SCIENTIFIC REPORTING.

A FEW weeks ago some specimens of an incandescent lamp were submitted for test to a gentleman whose name it is needless to mention. It was claimed that the new lamp, which is said to be outside the Edison-Swan patents, was also considerably less wasteful of electrical energy per candle-power than those now holding the monopoly of incandescent electric lighting. The lamps to which we refer were labelled for certain voltages, and in the table below the details of the experiments, which we have every reason to believe are correct, may be seen :—

Lamp Mark.	Actual Volts.	Current.	Candle-power.
98	98	·600 ampère	13·4
110	110	·525	12·7
106	106	·600	12·7
90	90	·800	14·13

We may incidentally mention that several samples of the lamp, which do not seem to possess much uniformity, probably on account of imperfections in a new manufacture, were also submitted to the same expert so long ago as last October, labelled 100 volts 16 candle-power ; but it was found that to bring them up to this luminosity required in the respective instances 104 to 106 volts. Being thus over-run, the result reduced to watts per candle-power showed a slight saving over the electrical energy generally assumed to be required in an Edison lamp incandesced to the same degree.

We believe it is safe to say that 60 watts for a 16 candle-power lamp is a maximum for any really good manufacture. Many makers or consumers would doubtless say—and if they feel convinced we allow too great margin we hope they will say—that 50 watts is nearer the mark, at all events when the filaments are first put into operation, the difference between old lamps and new in this respect being too well known to need further discussion.

This being so we wish to bring before the notice of our readers the report of a Professor of high renown, with every convenience at hand for conducting the

tests on the most scientific lines, and who, we believe, enjoys the confidence of the public in no ordinary degree. The lamps he was requested to examine were, we understand, selected from the same batch as those figuring in the above table, and this is his verdict after a comparison with Edison-Swan lamps :—" X's lamps consumed 3·12 watts per candle-power, Edison-Swan 4·29 watts per candle-power, thus proving that X's show an effective saving of 25 per cent."

Our readers will not fail to notice that there is no reference here to the voltage and measured candle-power of either X's lamps or those of Edison-Swan, therefore we need not question the intelligence of those who have even a slight acquaintance with lamp tests by commenting upon the value of such figures ; but upon examination of the foregoing table it will be seen that in X's lamps the labelled voltage in no case brought up the degree of incandescence to 16 candles, a result in conformity with previous tests. Calculating from these the electrical energy consumed it will be seen that instead of showing a saving of 25 per cent. over the Edison-Swan, X's lamps, they all demanded even more than those, probably old and half worn out, which came under the notice of the Professor.

Now we ask, is it fair to the owners of X's lamp patents, to the public, who will doubtless eventually read the report, to the electrical trades, and particularly to the Edison-Swan Company, to give such a vague, misleading, and absolutely valueless statement as that which we quote ? By overrunning we may make the watts per candle-power almost as low as we like, short of the breaking limit, or as uneconomical as needs be if working below the normal difference of potential at the lamp terminals, and the knowledge of a few simple facts like these would save much time, expense, and disappointed hopes alike to both financiers and inventors.

We almost feel inclined to offer to carry out a series of tests ourselves, and publish the results if makers would submit their lamps to our examination ; we would

at least test them under proper conditions, and give the necessary data from which experts and the public could form their own conclusions. Perhaps some of our readers will kindly favour us with some incandescent lamp figures as they exist at the present day?

### A CHALLENGE.

THE meeting of the Tramways Institute of Great Britain, which is discussed on another page, was, to the electrical fraternity, of interest only for the argument which took place on the score of electric traction. We need not here reproduce any of the points at issue, for they are fully set forth in their proper place; but we cannot let the matter slumber without an effort to revive so important and interesting a controversy. In our last issue we referred to the Elieson system as costing nearly three times the amount of the contract price per car mile, viz.,  $4\frac{1}{2}$ d., and we have now every reason to believe that the cost of electric traction on the Barking line is something like twice the contract figure. Data in our possession point to this result, and Mr. Willbond's assertions bear out to a great extent the likelihood of their accuracy; we cannot, however, at the moment publish them in detail, but we do challenge the General Electric Power and Traction Company, Limited, to bear out the statements which, on the authority of their managing director, appeared on page 72 of the REVIEW for January 17th of this year, when it was asserted that the working of the Barking line had shown it to be operated at a profit. This becomes all the more necessary when it is remembered that the Barking line formed one of the valuable properties for which the sum of £242,000 was modestly asked (*vide* articles on *Traction*, ELECTRICAL REVIEW for May 23rd and June 6th).

There is at the present moment too great a tendency to float companies, utterly irrespective of the merits of the structure on which they are based, and we feel, therefore, that it is best to be outspoken, for truth, like murder, will out, and there is no good in mincing matters at a crisis.

It is folly to work a line and pretend to be making a profit if the expenses are double the receipts; the only frank course to pursue is to state the actual facts, and then to seek for the means of reducing the working cost until traction by electrical energy can compete on its own bottom with the present means of tramcar propulsion.

Perpetual Motion  
Realised at Last.

A CORRESPONDENT sends us the following delightful cutting from the *English Mechanic*, which, with the electrophonoscope, we strongly recommend to the notice of enterprising company promoters. In either case it would be unnecessary to tell off an expert to examine into the stability of the business or the probity of those connected with the respective schemes:—

I wish to light my house with electricity, and it has struck me that I might do so without the aid of an engine. If I were to use two dynamos, starting one of them by hand, and using half of the current that I got from it to drive the other as a motor, letting the other half light the lamps, the motor would then be used for driving dynamo No. 1. I should be much obliged if you

would tell me (1) if this has been tried before?—and if not, could I take out a patent for it, as it is entirely my own idea? 2. How much wire should I put on each of the dynamos to light 20 8-volt lamps (not arc lamps)? And is it necessary to have the armature of iron, or would brass do as well? As I am very anxious to become an electrician proper, could you recommend any firm that would allow me to work for a few months in their shops, for which I would give my services, that I might get an insight into the practical work, as I understand the theory of the thing pretty well?—A WOULD-BE ELECTRICIAN.

Perhaps the best testimonial which this "Would-be-Electrician" could offer to a business firm is his self-made assertion that he "understands the theory of the thing pretty well."

Taking the Lead  
of America.

How Prof. Hughes and Mr. Preece must have chuckled over their huge Electrophonoscopic joke. It is not given to the lesser lights of science to conceive, much less to carry out, such an elaborate delusion which, it is not too much to say, has set the whole civilised world by the ears. Prof. Pepper, of Polytechnic fame, years ago devised many very clever optical illusions and he was looked upon as a scientific nobody; but it has been reserved for this age of enlightenment to laud to the skies the reproduction of an old trick with which every schoolboy is supposed to be familiar. "At last, it seems, says *Life*, "we have taken the lead of America in producing a triumph of electrical invention. To be able to see and converse with a friend on the other side of the Channel, for instance, will be an achievement that will simply abolish all the anxiety of absence and all the sorrow of parting. The 'Electrophonoscope' is certainly a marvellous advance in a science which of late years has made such giant strides, and it is most gratifying to know that we are indebted for it to the genius of two of our own countrymen." We fear *Life* does not know much of the subject upon which it treats. Fancy after getting rid of a "friend," one fondly hopes for ever, to be electrophonoscopically bothered by his presence from across the Channel! Luckily we are not likely to suffer any such misfortune until the Channel tunnel is constructed; then, if our two countrymen are still in existence and in full possession of their faculties, Heaven help us.

Increasing Loco-  
motive Traction  
by Electricity.

THIS subject is one which continues to excite interest in America; it is undoubtedly an important one in view of the adoption of electric locomotion with light vehicles. Mr. Elias E. Ries, whose experiments on the subject have been questioned as to their practical accuracy, are stated by Mr. C. Selden, in a paper read before the Railway Telegraph Superintendents' Convention in America, to be correct, as the result of experiments he has made. Certainly, according to the tests made with a model motor, the passage of a current between the wheels and rail, whether the latter were clean and bright, or highly greasy, increased the adhesion to a very marked extent. These results, it may be recollected, do not at all accord with experiments recently described in our pages; to what is this discrepancy owing? Mr. Selden, in his paper, admits that practical tests alone can determine whether sufficient power can be had from a proper dynamo and auxiliary engine to show even an increase of 25 per cent. in the adhesion in the case of a full sized locomotive. In fact, the question seems to be, to a great extent, whether the power required to give the adhesion may not be more profitably employed in increasing the power of the motor driving the engine, the latter being

more heavily weighted. It is stated that Mr. Ries is making arrangements for a trial which will determine conclusively the real value of the idea; the results of this trial will be awaited with interest, although we do not anticipate that an approach to electric welding in this form will prove advantageous. Adhesion between wheels and track must be obtained by some more simple method, for this can only be looked upon as a sheer waste of electrical energy at best.

The Overhead Wires Bill. A VALUED correspondent thinks our remarks last week on the overhead telegraph lines are not quite right. He points out that the Bill as it originally stood was one for the formation of subways in all streets, to compel gas, water, and electric companies to move their mains at their own cost into these subways, and afterwards pay a very high rent charge for the use of them. To those people who had already worked out a system of culverts, which are practically subways placed in the most handy position for serving the houses, the proposal was, of course, a very serious one; but at an early stage the subway clauses were abandoned, and the Bill was confined to the question of the regulation of overhead wires. Here is the point on which our correspondent falls foul, for he considers it would have been, and we think with reason, manifestly unjust to have compelled all the existing companies to place their wires underground at great cost, and then for the London County Council to issue licenses to rivals to carry on a complete system of overhead wires to serve identically the same district, and thus introduce an extremely unfair competition. Still, he thinks that even had the Bill passed through, the committee would have seen this unfairness, and restrained the County Council from giving such licenses where the district was already well served by subterranean conductors, and restricted the license to existing companies for the purpose of trunk lines to serve outlying parts or for scattered customers in thinly-populated portions of their area. Had such a contingency been provided for, our correspondent believes the Bill would have met the hearty support of those, himself included, who opposed it.

Overhead Wires. A Householder's Views. COMING nearer home our friend confesses that, as a house owner who had given permission for the erection of telephone poles and wires on his residence, he has a heartfelt sympathy with the speakers in the House of Commons who complained of the annoyance caused by the workmen who have to enter houses for the purpose of attending to the wires. "The British workman," quoting the writer's remarks, "is bad enough to manage when he is your own servant, but when he is not under your control his behaviour is such that it increases the discomforts of housekeeping enormously. The one subject of stair carpets is a perfectly correct one to mention. It must be admitted that a great deal of the domestic happiness of the average householder depends on the comfort and good temper of his servants, and I assure you that the tempers of the best of servants can be ruined by allowing workmen to tramp up and down stairs at all frequently. In all well regulated households the domestics do their work at certain hours, the house is cleaned down at a certain time, and if workmen come in after these hours and dirty the stairs and passages, as they invariably do, the equanimity of the servants is disturbed for the whole of the day. It is perfectly true also about thefts. It may be that the

workmen are perfectly honest, but they become the 'cat' responsible for all breakages and robberies which may have been committed by the servants themselves." He concludes as follows:—"If overhead wires are to be regulated and permitted, and attachments made compulsory, I am quite certain that the companies will have to maintain an outside ladder for the purpose of giving access to them, and that such outside ladders ought to be fixed much more frequently than is at present the case. They would act very effectually as fire escapes, and might be insisted upon with great advantage by the County Council. It should be fixed in a convenient situation at the back of the house in such a manner that it can be used as a fire escape, and provided with a gate or door at the bottom, so that it can be opened from the inside by anybody escaping, but would not be accessible to thieves or to anyone but the people owning the house or the officials of the overhead wire company." We cannot but think that the idea of the ladder is not happy so far as protection from burglars is concerned. Let our friend imagine a thief in his house, entering from the front, and, being disturbed, escaping by means of the very apparatus (opening it from the inside), which is intended to save life and defeat the ends of midnight prowlers.

Prospectus Making. HAD time and space allowed of such a course, we might have spoken last week at still greater length on the prospectus of the Okonite Company. In comparing its uncertain future with the present condition of the Silvertown and Telegraph Construction and Maintenance Companies, it must have been overlooked by the promoters that the profits of the latter powerful organisation are derived from the manufacture of goods which have nothing in common with okonite, and, although the reputation of the Silvertown leads is deservedly high, the profits from this source probably form a very insignificant part of those accruing from the whole undertaking. If, on the other hand, equally deserving firms had been cited, such as Henleys, the Helsby Company, Messrs. Walter T. Glover & Co., the London Electric Wire Company, &c., no such profits have been made, and as okonite must compete with the productions of these firms, it would have been only fair to have at least mentioned them. Moreover, to one who knows how difficult it is, and the unremitting care and attention required to work up a turnover in electric lighting with sufficient to pay a fair dividend, even on a modest capital, the task of attempting so to do on a sum of £440,000 appears stupendous. We should look upon the managing director who could successfully perform such a feat with respectful admiration.

The Rival Systems. WE shall be greatly interested to see what is said further on the subject of our last week's leaderette. It must be of great value to the trade in general to have the matter ventilated, and we do not for a moment think there is nothing to be said on the side of the alternating current system; but hitherto the companies using it have been remarkably chary in saying it, and if they do not come forward with explanations it is more than likely that a very bad impression will be made. It may further be pointed out that the balance sheets of a good many companies have been published, and in all cases the engine room costs of the alternating current appear to be excessively high, and hitherto no attempt has been made to explain them.

ON DESIGNING SWITCHES FOR  
ELECTRIC PLANTS.\*

By OLOF OFFRELL.

IN the early days of electric lighting very little attention was paid to the accessories of an electric installation, and especially to the devices known as switches. Naturally enough, as long as the dynamo and the lamp were in a primitive state, and, consequently, there was a great field for improvement in that direction, so long no attention would be given to less important matters, mere details, although quite important ones after all.

Only within the last two or three years have inventors turned their attention toward perfecting the switch, which has now become a *sine qua non* in almost every kind of electric installation; but we have now very ingenious and practical devices of this kind in the market.

The purpose of this article is to give some practical points on designing switches, brought out by experience.

One of the first points to consider in designing a switch is its capacity, that is, how many amperes of current it can safely carry over and through its contacts without appreciable heating. On this point there seems to exist a great difference of opinion. Not any two switches of the same rated capacity have approximately, or anywhere near approximately, equal contact surface. While a large contact surface is a decided advantage, we soon reach a limit, which we cannot pass without materially increasing the size and consequently the cost of the switch, and then the question arises—what is the smallest allowable contact surface in square inches per ampère to be carried that we can use with a factor of safety large enough to prevent any appreciable heating? The writer has found 0.01 square inch surface per ampère to be a good rule, below which it is not advisable to go. In arc light or constant current switches, which generally do not carry over 10 amperes, we can, and usually do, make the contacts a good deal larger, from 2 to 4 times, as we are here not so much restricted by a bulky appearance and cost as is the case with an incandescent switch.

It is always preferable to have contact surface on both sides of the lever carrying the current, *i.e.*, double contact springs; as, in this way, a better and more trustworthy contact is obtained. The contact springs must not be of too thin material; preferably they ought to be made of two or three thicknesses of spring copper, which are riveted to the binding post to which the conductor is secured. The very best way of securing the contact springs is to set them in grooves milled out for the purpose in the base of the binding posts and then rivet them. The contact spring ought to be split or cut up to almost its entire active length in two to four parts, depending upon the size of switch, because this makes it more flexible; and if there is an uneven spot on the contact surface of the lever, it will adjust itself to the unevenness and still make a good contact.

The contact springs or the lever must be so shaped that the lever leaves the contacts along their entire length at the same time. If it does not, the spark, in throwing the switch open, will concentrate itself at the point of last contact, and, in case of a heavy current, burn or fuse it.

The cross section of those parts of the switch that have to carry the current must have a conductivity according to the current to be carried, corresponding to 800 to 1,000 amperes per square inch.

The action of the switch must never depend upon springs, spiral or flat, through which the current passes, as the current will invariably more or less heat and take the springiness out of them, thereby causing the switch to give out.

Never let the pivot-bearing of the lever form one terminal of the switch, as the current in passing through the bearing will heat it, no matter how carefully it is

made, and sooner or later put the switch out of order. Each terminal ought to have contact springs for itself. This might make the bridge cost a trifle more, but it is a far better construction. The general practice to-day among leading manufacturers is to make such independent contacts for each terminal.

The set screws for holding the conductors in the binding posts ought to be large enough to stand a good tightening. Preferably they ought to be of iron, with square heads, so as to be tightened with wrench wherever the size of the switch allows it. The number of threads in the binding-post into which the screw engages must be large enough, so that there will be no danger of stripping the threads in tightening the screw.

In the case of a switch operated altogether by hand, without assisting springs, the lever ought to be provided with a stop device, which keeps the switch open, preventing it from accidentally closing the circuit. This is especially important in alternating current switches on the primary circuit, where an accidental closing of the circuit can endanger lives.

The handle is, of course, always made of wood or other insulating material.

The base of the switch ought to be made of fire proof, insulating material, for which slate, porcelain, hard rubber, moulded mica, &c., are suitable, and is now extensively used. If the base is made of wood, the front side ought to be covered with mica, so as to prevent the spark, that possibly can be formed, from setting the base on fire.

The cover in switches for low tension currents is generally made of metal, but it must always be insulated from those parts of the switch that carry the current. On the inside of the cover is generally placed one thickness of thin vulcanised fibre.

The practice so far has been to make all station switches, whether for high or low tension, open, *i.e.*, without cover; but the probability is that before long they will be provided with an insulating covering, at least where high tension alternating currents are used, so as to prevent accidents to the attendants.

The use of single pole switches is comparatively rare, especially in distribution of electrical energy at constant potential; switches are generally made with double poles, which in every case are to be preferred as by them a certain part of a circuit or a certain machine in a system can be completely disconnected by one movement of the switch lever. This is absolutely necessary where high tension alternating currents are used, and is compulsory wherever rules of a Board of Electrical Control or a Board of Fire Underwriters are adopted.

In order to prevent the possibility of the lever stopping at an intermediate point, whereby only a part of the contact surface would have to carry the whole current, resulting undoubtedly in destroying the switch, and further to prevent forming a spark at the instant of breaking the circuit, so-called snap switches have been invented. They are so constructed that the switch lever, once started by the operator turning the handle, is brought to its furthest position by means of one or two springs, independently of the movement of the handle. These springs are carried over the centre by turning the handle to a certain point, but act from that point independently of the handle. Thus all danger of the switch stopping on an intermediate position is prevented, as is also the forming of any destructive arc in opening the circuit.

For these reasons all switches outside of central stations ought to be made "snapping," *i.e.*, to quickly close and open the circuit independently of the speed with which the operator turns the handle. There are several meritorious designs on this principle in the market.

Constant current switches are made on a somewhat different principle from constant potential switches, as in this case the circuit must never be opened. The duty of a constant current switch is to cut out a certain loop or part of the circuit; but as the loop carries the whole current, it would interrupt the service on the whole line to open the circuit in the loop. The switch

\* *Electrical World.*

must therefore short circuit the loop before it disconnects it. Even these switches are made "snapping," although there is no absolute necessity for it if the short circuiting is properly done before the cutting out.

As a conclusion, I will say a few words about the latest developments in switches, which I have been recently engaged in designing, and in which the most important conditions for a first-class switch are fulfilled. These switches are to be used on the alternating circuits in connection with the underground cables in the New York subways to disconnect converters from the main circuit.

The requirements to be fulfilled by these switches are that they shall be water, moisture, and fire proof, and have an insulation resistance at least equal to that of the underground cables; in addition to which they must be so arranged that moisture cannot enter the insulation of the exposed ends of the cables terminating in the binding posts. The cables from the subway enter a cast iron box at one end, passing through a special kind of clamp screwed into projections on the outside of the box. These projections are made hollow to receive insulating cups, through which the cables pass to the binding posts. The cups are filled with insulating compound after the cables are in place, which then surrounds the bare ends of the wire, preventing moisture from entering the insulation. The cables leading to the converters pass through pieces of gas pipe screwed into corresponding holes on the opposite side of the box, and are soldered to them.

The switch is a double pole quick break switch, which is mounted on a hard rubber base. The switch stem projects outside the box through a stuffing-box in the lid, and can be operated from the outside by a handle, or the lid is screwed on and made water-tight by means of soft rubber and cement.

## ELECTRIC CAR TRUCKS.

By FRANK B. LEA.

IN a recent article (see the ELECTRICAL REVIEW of 27th June last, page 722) the writer endeavoured to show the possible course that will be followed in the development of electric traction so far as regards the type of car employed: and it was then seen that—apart from questions concerning the traffic—the most favourable ratio between paying load and dead weight of the car is obtained by using vehicles of large size.

That is, if the traffic may be fairly met by running large cars with heavy loads, the dead weight to be moved (and therefore the waste power exerted) is much less in proportion to what it would be with smaller vehicles designed to carry, perhaps, half the number of passengers.

It is assumed, therefore, that the electric tramcar should—for these reasons alone, and apart from other considerations—be made as large as possible. Of course there must be many instances of lines where a frequent and light service becomes necessary; but cases are perhaps equally numerous in which the traffic throughout a greater part of the day is met by running large cars at considerable intervals, any additional rush of traffic being accommodated by extra cars in the morning and evening.

There are, however, serious restrictions to the size of cars built upon the ordinary plan, not by any means the least of these being the unpleasant see-saw rocking motion ("teetering," as it is called in the United States) which appears to be an inevitable accompaniment of a long car having seats on the roof and provided with the ordinary central under-frame on four wheels.

Then, again, the rigid connection of wheels and axles in such a system places a low limit on the ability of the car to run smoothly and safely round sharp curves, such as are frequent on street railways.

A much pleasanter motion as well as extreme ease in traversing curves is obtained by the use of small four-wheeled bogie trucks placed one at each end under the

car frame, which pivots on them, and slews round on the pivots in traversing curves.

Advantages like these will probably more than compensate for the extra cost incurred, especially in view of the saving effected in the power required for traction.

There is at any rate no harm in assuming that many electric cars will and must be built on such a plan; engineers, indeed, are not wanting who predict for high speed railway work the almost exclusive employment of bogie cars with motors mounted on the trucks, as opposed to the use of independent locomotives.

On the point of tractive effort alone, it stands to reason that greater efficiency should be obtained where every wheel is a driver.

The Reckenzaun accumulator car of 1884 showed in this respect really more advance than others of a recent date, and as a type of vehicle, was well worthy of greater success than it appeared to obtain.

It is, however, useless to say that bogie trucks may be advantageously employed for electric tramcars without looking into the question as to whether such an arrangement is immediately feasible.

The average bogie truck is very like the proverbial chamber where it proved somewhat difficult to swing a cat round in safety; and just as there is a maximum space available for the motor, so also the latter has a minimum size for a given output.

The best proportions of both truck and motor details may be obtained from an examination of standard types. Thus, the ordinary bogie wheel measures, perhaps, 32 inches in diameter. At a normal speed of seven miles per hour, this implies, say, 80 revolutions per minute.

Assuming, for the moment, that there is only room for a single set of gear for reducing the motor speed, this reduction cannot well be less than in the proportion of 1 to 5. With a spur pinion on the motor spindle of 3·7 inches diameter, this should give a large gear wheel on the truck axle of, say, 18·5 inches diam. and a motor speed of 400 revolutions per minute.

An Immisch motor of the S.M. 8 type will give a maximum of 8 brake horse-power at this speed; and its over all dimensions are approximately 4 feet in length, 14 inches in depth and 22 inches in width.

Of course the ultimate decision as to what motors shall be employed must depend upon the condition of the line, gradients, &c., but in most cases it will be found amply sufficient to use, say, one motor (such as that above mentioned) on each bogie truck.

On level parts of the line a single motor would serve to work the car, the other meantime running idle; but both could be used in going up-hill with a heavy load.

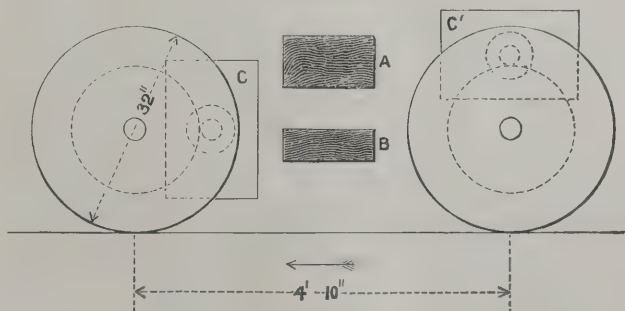

FIG. 1.

This plan allows of the driving truck being, as a rule, in the rear of the car, so that in case the forward wheels should miss the points at a junction and mount the rails, there would be less difficulty in drawing the car back.

Assuming, then, that these various advantages permit of or render advisable two end trucks for the car, and a motor upon each, it is not a very difficult matter to arrive at the amount of space available for motor and gear; and the annexed outline sketch will show what is possible with ordinary designs.

The wheels are of the common size adopted for trucks, viz., 32 inches diameter; and the wheel base is 4 feet 10 inches. At A is represented the spring plank upon which is fixed the pivot plate for the car frame to bear on; this plank goes right across the truck and is therefore shown in section, perhaps rather larger than is usual, but erring on the safe side for strength.

B is the bolster plank, to which are fastened the slide columns; between A and B are placed the powerful springs that give its characteristic easy motion to a bogie car. The plank B also traverses the truck, and therefore the motor and gear must be fixed on either side, not centrally.

C, C', represent the motor (seen endways) in two different hypothetical positions; in either case, of course, it would be supported in the well-known fashion, due originally, it is said, to Mr. F. J. Sprague, that is, with curved extensions from the pole pieces to the truck axle and bolster plank.

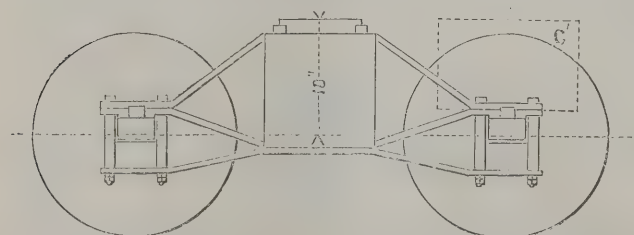

From the former the motor hangs by means of two ordinary bearings, whilst to the latter it is fixed with a double spring connection (tension and compression), so that, whether running backwards or forwards, there is a slight amount of play in the gear, which serves very materially to reduce strains.

It will be noticed that no details whatever of the brake gear have been shown; although these are, of course, very important and essential, they may yet be put aside for the time being until the motor question is decided. When that is done, there will be ample space and opportunity to bring in suitable appliances for braking the car, even if great modification of present designs should be necessary.

In the vertical position of the motor (shown on the left of the sketch) there is plenty of room above, between the motor and car floor, but very little underneath. The bottom of the motor reaches to within six inches of the rail level. In its horizontal position, the top of the motor would in all probability come too near the car floor and frame, unless the design allowed sufficient space for the motor between two adjacent floor stringers (running lengthways of the car), so that the framework might swivel when rounding curves.

Of the two positions, however, the horizontal one seems preferable owing to the greater ease of access; and it is a simple matter to raise the spring plank and pivot plate for the car frame so that the latter may clear the motor.

This implies a little difference in form of the standard diamond truck frame—as shown in the annexed sketch—but the change is merely one of form,

Sketch showing outside frame of bogie truck, with spring plank slightly raised so as to allow the car framework to clear the motor.

FIG. 2.

and does not add in any way to the cost.

By this means a clear space of 18 inches is obtained between the wheel centres and top of spring plank in its normal position; and this space should be sufficient to allow of the motor being fixed in position, as shown at C', above the axle.

As regards the length of motor, a space of 4 feet will more than house it comfortably; and on the usual rail track of 4 feet 8½ inches, there should be no difficulty in securing enough room between the wheels.

In tracing out conclusions from the details thus given, it may fairly be said—

1. That a minimum size has been allowed for the motor.

2. That, consequently, any material increase in the size of car, average load, &c., necessitating the use of a larger motor, will also offer considerable difficulties with respect to the fitting of such a motor upon the standard bogie truck.

3. That only one set of gear has been allowed for; and if a double reduction is desired, the whole design will need considerably modifying.

4. That although it seems a very convenient and simple device to use two motors on each car, there are many drawbacks to such a plan; not only is the first cost greater, but the working expenses also are heavier. Multiplication of machinery is always undesirable. This question, however, deserves separate consideration; there are *pros* and *cons* of importance to be looked into.

5. That it is quite possible to adapt the ordinary four-wheeled bogie truck for use with an electric tramcar, but the task presents considerable difficulties that need the exercise of great care, and it is not so easy as might perhaps at first appear.

## SHALL GAS UNDERTAKINGS SUPPLY ELECTRICITY? YES.\*

By ARTHUR F. GUY, Assoc. M.I.E.E.

THE natural inferences that would be drawn from the above title by gas managers would bear upon the all-important points:—First, what are the objects of so doing? Second, what profits would accrue therefrom?

The first is a question of policy, the second a question of £ s. d. This paper is an attempt to place fairly and concisely before owners of gas property the salient points in each case for their consideration as to the advisability and practicability of gas companies supplying electricity; the tone of the paper, as the title implies, is affirmative.

There are, perhaps, no more powerful organisations in the country than those of gas undertakings, and this is not to be wondered at. Throughout the length and breadth of the land they exist, from the largest cities to the smallest towns. The amount of capital invested in them is enormous. They yield good, and in some cases splendid dividends, and, in short, they are generally in a thriving and prosperous condition. The men who conduct them and have a voice in their proceedings are mostly those of influence and position in the district concerned, and the result is these properties form no small item in a nation's prosperity. The key to all this prosperity is, that they, up to the present time, have had no rival, gas being in universal use.

The general feeling prevalent among gas managers is that the electric light cannot affect gas, and in proof of this they point out the fact that since the electric light has been introduced the consumption of gas has increased. This statement is perfectly true, because artificial illumination is ever on the increase, whether it be by gas, candles, or electricity. Another argument put forward by them is that the electric light is in its infancy. Now this argument must be combated, because the term infancy is applied not only to usage but to the science of electrical engineering. The first point, namely, the "infancy of usage," is, perhaps, correct; but the second is not. We will consider the former first. There are some people who fondly dream that in this miraculous age of invention and discovery some means will come to light whereby any amount of electricity can be collected for next to nothing—in fact, a gift from Dame Nature, such as from some yet undiscovered chemical compound, or some peculiar condition of matter—and consequently that all our present costly and elaborate apparatus for generating elec-

\* Abstract of paper read before the Gas Institute.

tricity will become obsolete. No greater philosopher's stone was ever imagined.

With respect to the electric light being in its infancy as regards use, it is this fact that has shaped the title of the paper, for now is the time for the gas undertakings to act; it will soon be too late, and even now they have lost many a rich prize in the electric lighting line. Companies have been formed all over England to supply electricity, and the pick of the provisional orders have been relegated to either local authorities or private electric companies. This point joins issue with the supreme question, "Shall gas undertakings supply electricity? Yes;" and the reasons that justify this answer will now be given.

Consider the present state of affairs: there is a demand for the electric light; this demand is limited, but in time to come—and no one can say how soon that may be—this demand will be enormous. There are numerous reasons why it would be both politic and advantageous for gas undertakings to supply electricity.

The managing body of a gas works consists of men of great organising and administrative experience. The gas works from long establishment have obtained a certain prestige and influence in the district they supply. A manager knows his customers, and has acquired an insight into the weak and strong points of his district. The connection and vested interests pertaining to the gas suppliers are often numerous and deep-rooted. A gas undertaking has also the great advantage of easily raising capital, at a comparative low rate of interest; whereas new electric companies require financing, and the financing invariably leaves its mark upon them in the shape of a diminished dividend and an abnormally large capital. Many gas companies have large surplus monies in hand which could be invested in running the electric light at a profit to their shareholders. In the laying of electric mains they know exactly the position of their gas pipes, and so there would be none of that friction and petty annoyance that often arise when the electric light company comes on the scene. With regard to the erection of plant, where possible the electric light station should be located in or about the gas works. In some cases, no doubt, there might be a spare corner or outbuilding which might be made to accommodate the requisite machinery. At all events, the expenses incurred need not be so great as where a new site has to be acquired and a new building is specially erected and positioned by an electric light company. A large staff of men are employed at some gas works, some of whom are mechanics, and the assistance which these could render, both in erecting plant and maintaining same, would be of no small value. In the case of an electric light company, such men would have to be especially engaged, and paid at fixed salaries, whether busy or slack. Besides this, most of the office routine might be done by the existing clerical staff of the gas company. This, again, in the case of an electric light company, would mean specially engaged and paid clerks. An electric light company would require a board of directors, general manager, secretary, &c., all of which means a heavy draw upon the dividends, and this matter alone is sufficiently important to turn what might prove a good dividend into a bad one, or even none at all. In the matter of running expenses, there are numerous ways and means whereby a gas manager has the power of curtailing them. For example, the hot coke from the retorts can be utilised in starting the boilers, and some of the bye-products might be used as fuel.

Through being a large consumer of coal for making gas, steam coal ought to be obtained at much cheaper rates. The same refers to the purchasing of other material. The manager knows the best market for certain goods, and through long connection therewith ought to obtain advantageous bargains. The opponents of this paper will probably contend that if a gas works offer all these advantages it proves that it is badly managed, since, if well managed, there should be the strictest economy in everything, and not a man employed except his time be occupied fully, and not a

spare inch of ground in the works but that it has its use. This would be true if the management were perfect, but that point is never reached. No claim has been made that these advantages exist to a large extent, for that would certainly imply waste in the management; but that *some* advantage must be gained from each of these points under consideration cannot be denied.

It is the numerous small savings that in the total make up a respectable sum; however trifling each may appear by itself, when they are all added up at the end of a year it is just possible that they may come to a sum that will turn the balance to the right side of the ledger. It was stated that owners of gas property have great facility of raising capital. Now, with regard to this point, and also the opening up of streets for the purpose of laying electric mains, it is requisite that they obtain the necessary powers first from Parliament and the Board of Trade, and in the furtherance of this they occupy exactly the same position as any private individual or other company (for the second object they must first obtain consent from the local authorities). The same holds true where the owners of gas works are the local authorities.

If the gas companies are desirous of supplying electricity, those who choose should combine to obtain Parliamentary powers authorising them to raise capital and open streets for the supply of electricity, each company, of course, first obtaining the necessary consent of the local authorities.

The number of provisional orders that have been granted since the passing of the Amended Electric Lighting Acts in 1888 has been very great. The majority of these are possessed by private electric companies and the rest by local authorities; as for the owners of gas undertakings, there probably is not one which possesses an order, excepting Bradford Corporation.

Attention may be directed to America, where there are quite 100 gas companies supplying electricity in connection with the Thomson-Houston system alone. How many are supplying electricity by other systems is not known exactly, but they must come to a large number. And to show that electric light industries pay, it may be stated that the Thomson-Houston Company has invested in them £10,000,000 sterling, and each plant on an average throughout may be taken to be worth £20,000. Some pay 18 to 20 per cent., others less, and on the whole the average is 4 per cent. on the total capital; but it must be remembered that 25 per cent. of these stations are in their first year, and therefore as yet they have paid no dividend, because they are just starting. Taunton Electric Light Company paid 5 per cent. first year, 6 per cent. second year, 5 per cent. third year.

If a gas undertaking wishes to take up the supply of electricity, what they should do in the first place is to obtain the services of a competent electrical engineer, and let him advise them as to the cost and system to be employed.

If things continue like this, where will the gas company be in a few years' time? They will have in every district where there are gas works an electric light company competing with them, and then they will see that it would have been well if they had obtained a footing themselves. Assuming gas companies supply electricity, and looking into the far future, who knows but that gas works will eventually become electric light works, and that as the electric light enters into universal use, so will gas die out?

A comparison of cost between gas and electricity will now be made. The ordinary gas jet in private houses may be taken to give about 14 actual candle-power, burning 5 c. ft. of gas per hour. Let the price of gas be, say, 3s. per 1,000 c. ft. The cost of 5 c. ft. would be .18 of a penny for 14 candle-power, and for 1 candle-power the cost would be .013 of a penny per hour. Now, take the case of electricity. Assume that the price is 7½d. per unit. A unit signifies 1,000 watt-hours. An incandescent lamp of 16 actual candle-power absorb 56 watts; that is, 3.5 watts per candle-

power; and the cost of this is 1·40th or ·025th of a penny for 1 candle-power per hour.

This is for the supply of electricity alone. The cost of the lamp must now be considered. The lamp may be taken to last 1,000 hours, and costs 3s. 9d. Therefore the cost of 1 candle-power per hour will be ·0028 of a penny;

Hence total cost is...     ...     ·0250  
   ·0028

·0278 of a penny.

Therefore, gas costs ·013 of a penny per candle-power per hour; electricity, ·0278 of a penny per candle-power per hour. So that with gas at 3s. per 1,000 c. ft. and electricity at 7½d. per unit, the cost of the latter is little more than double that of gas, or, say, 6s. 2d. for an equivalent amount of light.

The following table gives the equivalent cost of gas for different prices of electricity per unit:—

Pence.

Per unit of electricity ...	4	4½	5	5½	6	6½	7	7½
Per 1,000 cubic feet of gas	41	46	51	56	61	66	71	76

Pence.

Per unit of electricity	8	8½	9	9½	10	10½	11	11½	12
Per 1,000 c. ft. of gas	81	86	91	96	101	104	110	115	120

The above is for incandescent lamps, not arcs. From the above table it will be seen that the approximately equivalent cost of gas is obtained by multiplying the price per unit by 10. Also, that every rise of ½d. per unit of electricity means a rise of 5d. per 1,000 c. ft. of gas. The price adopted in London is 7½d. per unit, or equivalent to 6s. per 1,000 c. ft. of gas. Gas works which supply electricity ought to be able to do it at 6d. per unit, and there are numerous towns in England where 5s. per 1,000 prevails for gas. This is bringing the price down in these cases on a par with gas. The gas committee of the Bradford Corporation supply at 5d. per unit, equivalent to 4s. 3d. for gas, and have a separate station for electric lighting. Local authorities, whether they possess gasworks or not, ought to be able to supply at this rate, so that when it comes to be a question of general adoption, and local boards throughout the country begin to establish central stations, there is this fact prominently before gas people, that the electric light can be supplied at equivalent cost of 4s. 3d. for gas. This is a price not out of the way, and certainly cannot be called expensive or high; and numbers will be glad to have it at this price for the sake of its superior illuminating power. Where great intensity of light is required, arc lamps afford a very cheap illumination; and for equal light with gas, its equivalent cost for gas would be only about 1s. 8d. per 1,000, or, roughly, the arc lamp costs only about half that of gas for the same amount of light—taking gas at 3s. per 1,000 c. feet., and electricity at 7½d. per unit. The reason of this is that for the same amount of electric energy the intensity of light emitted from an arc is about four or five times that from an incandescent lamp.

Before closing this paper, a few items will be given concerning the cost of installing plant. Take the case of a plant for 2,000 incandescent lamps, run by high tension alternating current dynamos and transformers, the wires being overhead, and supplying six miles of route. The total cost of putting down this plant, in the precincts of a gas works where a building could be appropriated, would be about £8,000 or £4 per lamp. It is found that on an average only two-thirds of the lamps installed in any premises are alight simultaneously; therefore, a capacity for 2,000 lamps means 3,000 installed in houses. To assume that each lamp installed is alight for 800 hours per annum is very

moderate. This, then, equals the full load, or 2,000 lamps for 1,200 hours. 800 per hour signifies a lamp burning from dusk to a trifle after 8 p.m. every day throughout the year.

2,000 lamps for 1,200 hours consume  
2,000 × 1,200 × 56  
= 134,400,000 watts  
= 134,400 units

and at 6d. per unit this equals £3,360.

The total working expenses, including 7 per cent. for depreciation of plant, would not come to more than 4½d. per unit, or £2,520. With a revenue of £3,360, this signifies profit of £840, yielding a dividend of 10½ per cent.

That the above is practicable may be proved by stating that the Electric Company at Rochester supplies electricity at 6d. per unit, and can pay a dividend of 11 per cent.

## FIRE IN AN ELECTRIC LIGHT STATION.

AT 9.15 o'clock p.m., on Wednesday, the 11th inst., the central electric lighting station of the Manhattan Electric Light Company, located at the corner of Eightieth Street and Avenue B, in New York, was struck by lightning and very heavily damaged by fire. The lightning did not strike one of the company's circuits and come into the building over the wires, says the *Electrical World*, for in that case the bolt would have gone to earth through the lightning arresters placed upon the lines, but it struck the roof of the building itself and originated the fire directly underneath the tower through which the wires enter, and at the top of the incandescent light switchboard, and from this point the flames spread rapidly throughout the building wherever there was any combustible material to be consumed.

The equipment of this station was of an excellent quality, the building itself being of brick, with fire-proof floors and partition walls, although the tower furnished a passage-way for the flames from the first to the second story. Customers using about 20,000 incandescent lights were supplied from 18 Slaterry alternating current dynamos, while the arc lights were run from 11 machines of the Brush and Thomson-Houston types. The two switchboards, one for the arc lighting circuits and the other for the incandescent lighting, although near together, were kept entirely separate. Between them was a new and nicely furnished gallery, which had just been fitted up for the regulating devices of the incandescent circuits. The floor above the dynamo room was occupied by the offices and store rooms of the company, while upon the floor beneath was the engine room. This contained four 750 horse-power compound condensing engines, and two 350 horse-power high-pressure condensing.

The damage done was confined to the dynamo room and the offices and store rooms, as the fire did not reach either the engine or boiler rooms. Out of about 30 machines only two or three of the arc dynamos, that were located furthest from the origin of the fire, escaped such serious injury as to make them unfit for use. The 18 Slaterry dynamos sustained an average damage of perhaps \$1,500 each, although it is difficult to tell just what the damage will be until the machines are put into the shop and overhauled. The arc light dynamos, being further from the burning switchboards, were not so seriously damaged, although they were considerably injured by water. The incandescent circuit switchboard, together with 280 switches, 64 ammeters and about 70 voltmeters, was entirely destroyed. Fifteen compensators, 18 rheostats, and many other accessories were rendered worthless. The arc light switchboard, with its bank of switches, was partially consumed, and will have to be rebuilt and refitted. Every belt in the station was so badly burned as to require an entirely new outfit. Of the four large 48-inch engine belts, only one remained that could be repaired so as to be fit for use. Considerable damage was sustained upon the

stock, and upon the books, prints and drawings kept in the office of the engineering department.

The work of reconstruction and recuperation was begun at once after the fire, and the manner in which this has been done, and the rapidity with which the plant has been again put into running order, reflects great credit upon the management of the station, and is an illustration of the marvellous capabilities of a well-planned system of electric lighting. The night after the fire about one-half of the arc lights and 12,000 incandescents were supplied with current as usual, while on the second night 17,000 incandescents were connected, and on the third night not far from 20,000 lights. The company was able to make this fine showing through the kind assistance of its very obliging business rivals. Many of its lighting circuits, of which it has nineteen in all, were connected to other stations in the city, and have since been supplied by current from these stations. Meanwhile the company has been putting its own plant in running order. Five new Slaterry dynamos were received soon after the fire from Ft. Wayne, Ind., by express, and other machines were sent for and received from the Thomson-Houston factory at Lynn, Mass., while the electric lighting companies in New York have very kindly loaned such machines as could be spared from their own equipment. By these various means the company has been enabled to replace in less than a week at least two-thirds of its entire plant, although, of course, this hasty installation has necessitated much work of a merely temporary character. When it is considered that the entire plant, with the exception of the engines, boilers and shafting, was rendered useless until replaced by new machinery, it must be admitted that the results obtained in so short a time reflect great credit upon Mr. E. A. Leslie, the general manager of the company, to whose energetic action much of the wonderful recuperation of the damaged plant is due.

#### COST OF ACCUMULATOR TRACTION.

AT the annual meeting of the Tramways Institute of Great Britain and Ireland, to which we briefly referred last week, several papers were read and discussed. The reading of papers before the Institute was a welcome innovation, as none had been introduced at previous meetings. It is, however, only to three of these that we need refer. The first was descriptive of the Birmingham cable tramway, and the only interesting facts elicited were that the initial cost of a single line one mile long ranged from £10,000 to £15,000, a double line of the same length, £25,000; and that the cost of working per car mile was 8½d. for a car carrying 70 passengers. As compared with horse traction, which averages 6½d. per car mile throughout the United Kingdom for cars accommodating 52 passengers, the cost for cable haulage is slightly greater.

The other two papers treated of electric traction. One of these was a mere recapitulation of the different systems and numbers of electric tram and railways in operation in the United States, the information being mainly derived from monthly magazines. The other paper, by Mr. A. Dickenson, C.E., of Birmingham, referred principally to electric traction in Europe. The author referred to the Julien system of electric traction—whatever that may be—and gave a detailed description of the accumulator cars shortly to be introduced on the Bristol Road route of the Birmingham Central Tramways Company. Turning to the Barking electric tram-cars worked by the (now) General Electric Power and Traction Company, Limited, at a contract price of 4½d. per car mile, he stated that if the whole of the tramways in the United Kingdom had been worked last year at that figure the result would have been a saving of

£200,000! The speaker, in conclusion, asserted that the Barking line had resulted in a small profit to the contractors.

The discussion on the two traction papers was taken together. Mr. A. Willbond asked for the authority for the statement that the Barking cars were a commercial success. The reply from Mr. Dickenson was that he was authorised by letter from Mr. R. Macpherson, one of the directors of the contracting company, to state that such was the case. Mr. Willbond then said that he would produce Mr. Macpherson's own figures, which showed conclusively that the line was a failure from a commercial point of view. This brought forth more than one protest from Mr. Dickenson, but it having been put to the members of the institute, who evidently not only relished the idea of the statement being contradicted, but who also desired not to be gulled on the subject, the speaker was permitted to proceed. He stated that from the opening of the line on the 14th June to the end of December last year, the total mileage attained by the cars was 34,366 miles, and that the total amount of profit made during that period, according to balance sheets shown to him by Mr. Macpherson, did not exceed £70. This sum of about £70 was realised after paying drivers' wages, expenses at charging station, including coal, oil and water, but exclusive of the engineer's salary. It, however, excluded one of the most important points in electric traction, namely, the cost of accumulator renewals. According to the generally admitted cost of renewing the accumulator plates, that is, from 1d. to 1½d. per car mile, or an average of 1¼d., the cars must have been worked by the contractors at a loss. Taking the actual mileage of 34,366 miles and multiplying this by 1¼d., the cost for renewals alone, without allowing anything for the depreciation of motors, gearing and for station plant, amounted to £178 19s. 9d. This showed, continued the speaker, a loss for the first 6½ months' operations of £108 19s. 9d. Therefore, the cost per car mile was 5¼d. without considering the expenses previously mentioned.

Several other gentlemen took part in the discussion, which was of a lively character. Mr. Dickenson again protested that Mr. Macpherson had given him authority to make his statement regarding the Barking cars, but he appeared to be under the delusion that two individuals could not know anything about the same subject. The president, Mr. Carruthers-Wain, said, however, that Mr. Willbond's assertions as to the commercial failure might probably not apply to the half year just ended, and that *possibly* the statement of Mr. Dickenson did so apply.

Mr. Joseph Smith, the chairman of the Birmingham Central Tramways Company, and upon one of whose lines the previously mentioned accumulator cars will shortly commence service, laid great stress upon the cost of generating the current, and stated that time only would show the *actual cost* of accumulator traction per car mile. He hoped at next year's meeting of the Institute to be able to lay before the members data concerning the actual working cost of the self-contained cars, which were to do service on one of his company's lines. Mr. Smith's remarks were well received, and the consensus of opinion seemed to be that accumulator traction at present was not commercially successful.

To the above we may add that if the Barking line is a paying concern, why did not the contractors send a qualified representative with *bonâ fide* data showing that such was the case instead of authorising one gentleman to make the assertion—which he could not prove—that the running of the cars had resulted in a small profit. Again, in addition to the data furnished by Mr. Willbond, there must be considered the salaries of the secretary and clerk, office expenses, interest on capital outlay, &c. Moreover, as a fresh set of plates were supplied for the batteries during April—May, the cost of these would at their then market price amount to over £1,000. We have, therefore, no reason for thinking otherwise than that the Barking line so far is a failure from a commercial aspect.

A SYNTHETIC STUDY OF DYNAMO  
MACHINES.*Continued from page 638.)*

## VIII.—ARMATURE REACTIONS—(continued).

IN section VI. we saw that the E.M.F. of any machine was expressed by the equation

$$E = \frac{N s W}{10^8},$$

where  $N$  is the number of lines of force passing into the armature core from each pole-piece;  $s$  the number of revolutions per second, and  $W$  the conductors on the exterior. This is true for multipolar machines if the armature is coupled up in as many parallels as there are poles, and the output, multiplying by  $C$  is, therefore:

$$E C = \frac{N s W C}{10^8}. \quad (7)$$

In our last article we observed that it was more convenient to express the load on the armature by the volume of current it carries, this being the product of the conductors on the exterior, and the current in each.

The volume is equal to  $\frac{W C}{p}$ ; whence substituting for  $W C$  its value, we have, in terms of the volume  $V$ , the output:

$$E C = \frac{N s V p}{10^8}, \quad (8)$$

$p$  being, as before, the number of poles. We have now two expressions which we shall find most convenient to apply to the design of machines. We have first the volume, which is expressed in terms of the induction in the air gap and the gap dimensions, and, secondly, the output given in terms of the volume, number of poles, and other dimensions. Without fixing for the moment these latter, we may say that the considerations which determine the output, so far as the armature is concerned, are known, but before the magnetising force required to produce the requisite induction in the air gap can be ascertained, it is necessary for us to consider the component of the armature windings, weakening the field.

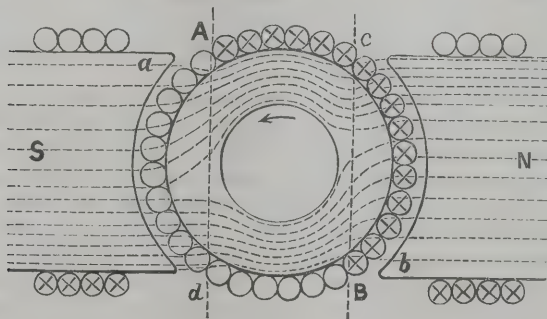

FIG. 148.

The brushes being placed at A and B, fig. 148, we have seen that the convolutions lying between the two vertical lines, A  $d$  and  $c$  B, directly oppose the forward induction, as they form a belt of conductors having a width equal to twice the angle of lead, in which the current flows in an opposite direction to the current round the magnets. If  $A_2$  be the ampère turns on the armature, and  $\lambda$  the angle of lead, the ampère turns weakening the field are  $\frac{4 \lambda A_2}{360}$ , or calling  $W$  as before, the conductors counted all round the exterior, and  $C$  the total current, there are on the armature producing this effect  $\frac{2 \lambda W}{360}$  turns of wire, carrying a current of  $\frac{C}{2}$  ampères. This is the same as if there were wrapped

round the armature, in a plane perpendicular to the direction of the field,  $\frac{\lambda W}{360}$  turns of a conductor,

having flowing in it, but in an opposite direction to the current in a field coils,  $C$  ampères, or the same current as carried by the armature. The demagnetising force in ampère turns is thus  $\frac{\lambda W C}{360}$ . In this expression the lead,  $\lambda$ , is assumed to be known, though, as already mentioned, its exact predetermination is a matter of some doubt.

In order to compensate the weakening of the field, the magnetising force on the magnets must be, according to this equation, increased by an amount equal to  $\frac{\lambda W C}{360}$  ampère turns. We have had no opportunity of

testing, experimentally, the accuracy of the expression, but so far as judgment can be given from what has been already done, this formula always gives a value for the ampère turns too low. It seems that the problem does not admit of such simplicity of treatment as here assumed, or probably other reactions are combined with the one in question, making it impossible to estimate accurately the effect produced by each. As regards drum armatures, Prof. Thompson remarks that a very convenient approximation to the back induction of the armature may be made by simply counting the number of armature conductors exposed between the horns of the polar surfaces, and multiplying this by half the armature current. He further explains that the nearness of this assumption arises from the fact that in most modern dynamos, for all currents, the point for the brush is at a position not far from that corresponding to the passage of the commutated section from the idle space between the pole pieces into the working space in the polar gap. According to this statement, the angle between the pole tips is  $2 \lambda$ , and the conductors between the tips are  $\frac{2 \lambda W}{360}$  which, multiplied by the half current, gives  $\frac{\lambda W C}{360}$ , the expression before obtained. On the occasion

on which Prof. Thompson made the above statement Dr. J. Hopkinson observed that, so far as he knew, the lead of the brushes in the best machines was never so large, and that the brushes were consequently behind the polar horns. The two statements appear difficult to reconcile, but if we take both as representing facts, omitting the explanation attempted by the former speaker, we come to this, that since the angle of lead is always less than half the angle between the tips, the formula gives too low a value, seeing that to obtain the actual ampère turns required for compensation we have to assume the lead to be greater than it really is. Doubtless, makers of dynamos have rules of their own for the compensating ampère turns to be added to the magnets; but very little in the way of experimental evidence on this point has been published, and the dearth of figures concerning a matter so important is much to be regretted. On the subject of drum armatures we have no evidence whatever, and very little regarding cylinders. Last February Prof. Ayrton made some tests on a Manchester dynamo, the results of which afford us a little information. This machine had 320 conductors on its armature, which carried a current of 31 ampères. The angle embraced by the pole pieces was presumably  $140^\circ$ , and we will assume that the lead was  $20^\circ$ , which would bring the brush just under the pole tip. Under these circumstances our formula would give for the magnetising force to com-

pensate the back induction  $\frac{20 \times 320 \times 31}{360} = 550$  am-

pères turns, whereas the value of the compensating ampère turns actually required was 1,200. In June, 1888, Mr. Esson made some experiments on a Phoenix dynamo, in which the weakening effect due to the armature was also observed. The armature of the machine tested carried a current of 92 ampères, and

had wound on it 180 conductors. The angle embraced by the pole piece was short, being only  $112^\circ$ . The lead of the brushes we will assume to have been  $30^\circ$ , though Mr. Esson thinks it was less than this; it was certainly not more. Under these circumstances the ampère turns required for compensation, as given by the formula, would be  $\frac{30 \times 180 \times 92}{360} = 1,380$ , but ex-

periment showed that the extra magnetising force required was 2,610. The method of conducting these experiments is to run the machine at a constant speed, while having some arrangement by which the exciting current can be easily varied and accurately measured. The difference between the ampère turns required on the magnets when the machine is running without current in the armature, the brushes being on the no-load line, and those required when the full current flows and the brushes are adjusted to their non-sparking point gives, the E.M.F. being in both cases the same, the magnetising force required for compensation. These are the only experiments of which we know referring to this question.

It is apparent, then, that a very considerable discrepancy has to be accounted for. Probably it is much less in drum than in cylinder machines, but for the latter it appears that there must be allowed about twice as many ampère turns for compensation as the formula indicates. This shows that the formula is not complete, that there are in fact factors omitted which considerably modify the results. In the absence of complete data the ampère turns necessary have to be determined experimentally by the makers for the different designs they manufacture. For the Phoenix machines the ampère turns which have to be added to the magnets to compensate the weakening are given by Mr. Esson as '66 of the ampère turns on the armature. This is probably a fairly approximate coefficient for other Gramme wound machines

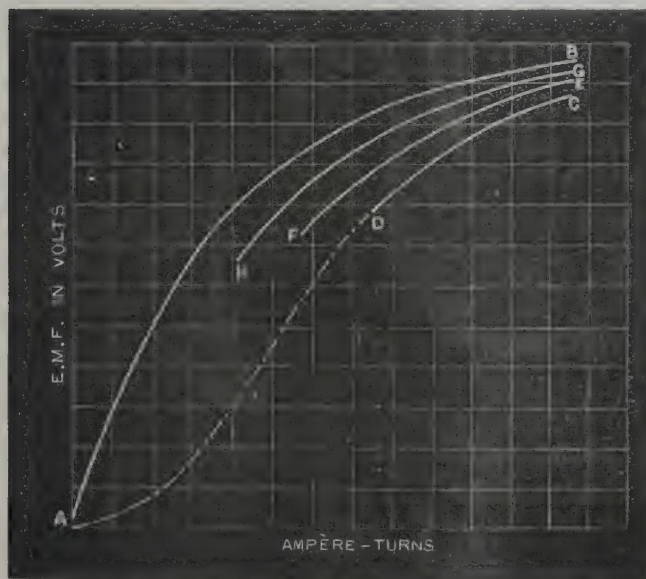

FIG. 149.

The weakening effect of the armature on the field may be conveniently recorded for any particular machine by a series of curves, as shown in fig. 149. The machine is run at a constant speed, and the field magnets separately excited to determine the relation between the magnetising force and the induced E.M.F. In the figure the former is represented by abscissæ and the latter by ordinates, the curve, A, B, being obtained while running without a current in the armature. The curve, C, D, is obtained when there flows in the armature the greatest permissible current, this being kept constant while the strength of the field is varied and the brushes adjusted to the sparkless position for each reading. The curve stops at D, because with a farther weakening of the field a non-sparking position cannot be obtained, and a less E.M.F. for that

particular armature load and speed becomes impracticable. If, in spite of the sparking, the observations were continued with a gradually diminishing strength of field a continuation of the curve, as shown by the light dotted line, D, A, would be obtained. The curve, E, F, is obtained with a less armature load, and G, H with the load still further reduced. It will be observed that as the ampère turns on the armature get less the curve can be carried lower, or, in other words, the field can be weakened down to a greater extent before we arrive at the sparking point. From this diagram we learn everything which requires to be known respecting the magnetic circuit of the particular machine from which the results it represents are obtained. It tells us the ampère-turns required for any induction on open circuit, and how many ampère-turns must be added to compensate the armature reaction, or how many will be required to raise the E.M.F. by a required amount with any current flowing. That the ampère turns required to compensate the load are fairly constant for all values of the induction will be apparent.

In determining the magnetising force required for multipolar machines, we found it often advisable to ascertain the ampère-turns required for each individual field coil, considering the induction which had to be produced, and the lengths of the several components of that part of the magnetic circuit through which each coil had to force it. As in finding the magnetising force on the assumption of no armature reactions, this treatment was most convenient, so in dealing with the armature reactions it is found most convenient to determine the ampère-turns which are required for each pole to compensate the weakening effect, the ampère turns for each coil being then ascertained accordingly as the field is of the single or divided circuit class, and as there are one or two magnetising coils on each circuit. It will be remembered that in the divided class of field the induction from each pole takes a double path through parallels of magnetising coils, while in the single class, though the induction may take two paths, these are combined in one where the coils are, so that the whole of the lines from the pole pass through each coil. Whether the machine is bipolar or multipolar the compensating turns have to be determined experimentally—our object at the moment being to show that their value is determined by similar considerations and that the allowance for machines having four or more poles may be easily deduced from that provided for machines with two poles.

The ampère turns on the armature, by which each pole is directly influenced are found by dividing total volume of current the armature carries by the number of poles. As mentioned in our last article, we may imagine the conductors to be replaced by a cylinder of copper divided at the brushes into as many segments as there are poles, the sheet of current in each producing a direct effect upon its corresponding pole. The effect is seen first in the distortion or twisting of the field; secondly, in the weakening. On the assumption that the brushes are close to the tips, it will be remembered that all the conductors under the pole piece are concerned in producing the distortion, while those lying in the space between the tips of the adjacent poles produce the weakening. In the two-pole machine we saw that the magnetising force producing the back induction was  $\frac{\lambda W C}{360}$ , or for each pole

$$\frac{\lambda}{360} \times \frac{W C}{p}, \text{ where } p \text{ is the number of poles. But in}$$

terms of our previous definition,  $\frac{W C}{p} = v$ , the volume which is carried by the armature, and we get, therefore, as a final result for the ampère turns demagnetising each pole,  $\frac{\lambda v}{360}$ , this expression being in terms of the volume, and like previous ones, independent of the number of poles.

It is probable that in multipolar machines the dis-

crepancy between the ampère turns which have to be added for each pole piece, and the number indicated by the formula is as great as in machines having two poles. Twice as many may be required in this case as in the other, and as already observed, farther information on the subject is much needed. Until this is forthcoming, however, it is sufficient to have shown that the same *kind* of expression is true for all types of machine.

(To be continued.)

## EDINBURGH EXHIBITION.

### EXHIBITS.

(Continued from page 722, Vol. XXVI.).

No. 59. Messrs. Paterson and Cooper exhibit a good assortment of dynamo machines, arc lamps, measuring instruments, and general electric light fittings. This

signed for ship work. For saloons and cabins the lamp brackets and pendants are silver plated and of artistic design, while for deck and cargo work, fittings of a very strong design are employed suited to the rough work for which they are intended. The portable cargo lantern has a cluster of three 16-C.P. lamps, and is provided with a strong outer guard for protection; the hold lamp fitting is made of heavy iron, and has hinged to it a strong shutter, so that when closed up cargo can be placed in the hold against it without fear of its being damaged. In ordinary cases these lamps are only used in port when loading or discharging cargo, but should the hold be used for cattle or sheep they are very serviceable at sea. The regulation types of mast and side lamps fitted electrically are shown, each having two 16-C.P. lamps. It is claimed that the light is visible at a greater distance and clearer than that from oil lamps; also that in stormy weather they will burn perfectly steady when it would be difficult to keep oil lamps burning. Another appliance used in connection with ship work and shown at this stand is a small motor fan or saloon punkah. These have been applied

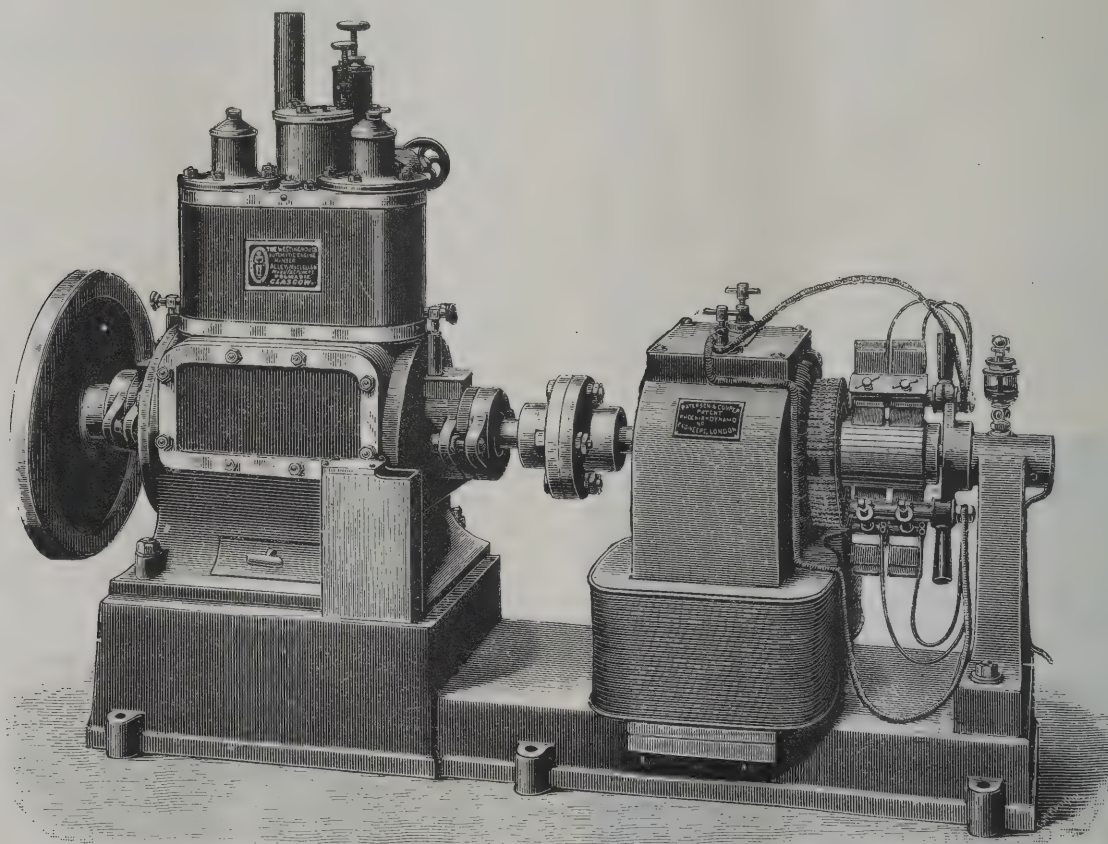

FIG. 1.—PHOENIX DYNAMO AND WESTINGHOUSE SPECIAL ENGINE.

firm's standard pattern of single magnet Phoenix dynamos is well known, and has been described in our columns on previous occasions. Different sizes are shown, suitable for belt or rope driving, and in addition is exhibited a Phoenix dynamo coupled direct to a "Westinghouse Special" engine, particularly suited for ship lighting or for employment where the saving of space is an object. This combination is shown in fig. 1, the cast iron bed plate which supports the engine taking the place of the usual machine bed, and forming, as does the latter, the yoke to the magnet. At a speed of 600 revolutions per minute the dynamo gives 45 ampères and 100 volts, furnishing power sufficient for 75 lamps of 16 C.P. each. The engine works at a steam pressure of 100—120 lbs. per square inch, and the speed is automatically governed. The cylinders are  $4\frac{1}{2}$  inches in diameter, and the stroke 4 inches.

Amongst their electric lighting accessories are to be seen polished slate distribution tablets, for ship work, fitted with ammeter and voltmeter, fuses, and spring switches labelled with the names of the various circuits; also a large number of fittings specially de-

signed for ship work. For saloons and cabins the lamp brackets and pendants are silver plated and of artistic design, while for deck and cargo work, fittings of a very strong design are employed suited to the rough work for which they are intended. The portable cargo lantern has a cluster of three 16-C.P. lamps, and is provided with a strong outer guard for protection; the hold lamp fitting is made of heavy iron, and has hinged to it a strong shutter, so that when closed up cargo can be placed in the hold against it without fear of its being damaged. In ordinary cases these lamps are only used in port when loading or discharging cargo, but should the hold be used for cattle or sheep they are very serviceable at sea. The regulation types of mast and side lamps fitted electrically are shown, each having two 16-C.P. lamps. It is claimed that the light is visible at a greater distance and clearer than that from oil lamps; also that in stormy weather they will burn perfectly steady when it would be difficult to keep oil lamps burning. Another appliance used in connection with ship work and shown at this stand is a small motor fan or saloon punkah. These have been applied

to several of the eastern-going ships, fitted by Messrs. Paterson and Cooper, and the cool atmosphere provided by their use has added much to the comfort of the passengers. The fan attached to a small electro-motor is placed near the end of the saloon, and furnishes a continuous supply of cool air, a switch for turning the driving current on or off being conveniently situated under the control of the steward. Models of several of the steamers which Messrs. Paterson and Cooper have fitted with electric light are shown. Amongst these is the ss. *Parisian*, a handsome vessel, 440 feet in length, built for the Allan Line Mail Service by Napier and Sons, of Glasgow, in 1881. Her carrying capacity is 9,663 tons, and her engines are of 6,000 horse-power. She is fitted with 500 electric lamps, the current being supplied by two Phoenix dynamos, each belt driven from a separate high speed vertical engine. Another model shown is that of the ss. *Perth*, the fourth vessel fitted by Paterson and Cooper for the Dundee, Perth and London Shipping Company. This vessel has just been completed by the builders, Messrs. W. B. Thompson & Co., of Dundee,

and, in addition to the ordinary lights for the cabins and passenger service, special fixed lights are provided for the cargo work in the holds and on decks. In addition to the models several photographs of the steamers fitted by the firm are also on view.

The Phoenix arc lamp, manufactured by the firm, has a place at the stand, and is shown with its protecting cover removed in fig. 2. This lamp is of the differentially wound class, and is equally well adapted for burning in series on a constant current circuit or in parallel on a constant potential circuit. In the drawing, A represents an electro-magnet wound with coarse and fine wire coils, the pole pieces, P, acting upon an armature, K, fastened upon a frame, H, D, pivoted at F. The frame carries a brake wheel, B, on

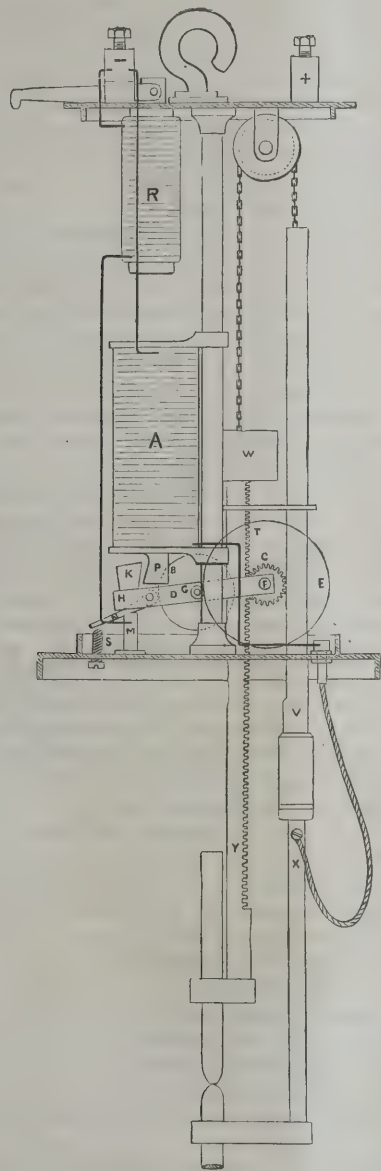

FIG. 2.—PHOENIX ARC LAMP.

the axle of which is fastened a small pinion, G, and a brake lever, N, made to grip B by a helical spring attached to the frame. The pinion, G, gears into the larger toothed wheel, E, on the axis of which is a pinion, C, engaging with the rack, Y, of the positive carbon rod. This rod carries a weight, W, which in descending enables the negative rod, V, X, to be lifted. When no current is flowing the brake lever, N, rests on the screw, S, which releases the brake wheel and allows the carbons to come into contact. The action of the lamp is as follows:—The current enters the right hand positive terminal, passes through the framework of the lamp to the rod, Y, and thence to the positive carbon. It returns by the insulated rod, X, and flexible cord attached to it, passing through the coarse wire coils on A, and then to the negative terminal.

The magnet attracts K, raising the frame, H, D, this causing the lever, N, to grip the brake wheel, and the toothed wheels, E and C, turning, the rod Y, is lifted, and X lowered, the arc being thus formed. As the carbons consume the difference of potentials at the lamp terminals rises, the current in the fine wire coils round A, which are a shunt to the terminals, consequently increasing. This weakens the electro-magnet, A, and allows the frame, H, D, to fall gradually, and the carbons to approach each other. When the lever, N, comes in contact with the screw, S, the brake is released, allowing the carbons to approach as the consumption continues. While the lamp is burning the end of the lever remains quite close to the screw. If the carbons burn out, or from any other cause the circuit through them is broken, the frame, H, D, drops on the insulated pillar, M; this completes the circuit from the lamp frame through the German silver resistance, R, to the negative terminal, thus preventing a break in the continuity of the circuit when the lamps are in series. When burning in parallel on a 65-volt circuit, the bye-pass resistance, R, is removed. The pole-pieces, P, and armature, K, are shaped so that for the same current and difference of potentials the pull on the frame is in every position similar, but should the current or difference of potentials alter, a small movement of the frame at once adjusts the arc to its normal length. A dash pot attached to the armature checks any sudden movement due to impurities in the carbons, &c. These lamps are installed at Peter Robinson's, Oxford Street, and Regent Street houses, at the Albert Institute, Dundee, and in many other important installations.

A variety of electrical measurement instruments, for which the firm has justly a reputation, is, of course, exhibited. Among these are the well known permanent magnet Ayrton and Perry instruments, which the firm has manufactured since their first appearance, and which still find a good sale. Several Phoenix dead-beat electro magnet ammeters and voltmeters are also shown, the controlling force in these being furnished by a strong spring instead of by the weak directional effort of an electro-magnet with a very small core. These instruments are made to measure currents up to 2,500 ampères. Cardew voltmeters of the latest pattern, as well as all forms of instruments used for electric light testing, are to be seen.

A model of a new system of railway carriage construction, designed by Mr. R. M. Short, is shown, the carriage containing first, second, and third class compartments, with lavatories, &c., electrically lighted. Though not in connection with electricity, Messrs. Paterson and Cooper have a model on view of Captain Anderson's patent hold-handy ladder, which is designed to supersede the dangerous hold ladder now in use. It affords easy access to the holds, and is of great convenience to shipowners and surveyors, when inspecting cargo, &c. The ladder is fitted on the ss. *City of Vienna*, and other steamers of the City Line.

## OBITUARY.

### JOHN BOURDEAUX.

IT is with great regret that we record the death of Mr. John Bourdeaux, submarine superintendent of the postal telegraphs on Her Majesty's telegraph cable ship, *The Lady Carmichael*, stationed at Dover. He died on Wednesday, the 2nd instant, at 8.0 a.m. Born in 1834 he had just completed his 56th year. Mr. Bourdeaux joined the Electric Telegraph Company when 15 years old, in the early days of telegraphy, and after two years' service with them joined the Submarine Telegraph Company. He went to Dover in 1862, and was submarine superintendent for the laying and repair of the English Channel and North Sea cables for nearly 30 years. Mr. Bourdeaux had a busy and anxious time in connection with the

transfer of the Submarine Company's business and plant to the Post Office. He had the double difficulty of looking after the interests of his old employers, and of making friends with the new ones; and, in assessing the value of cables, whose life and condition was extremely varied, much tact and diplomacy was required. During the tests taken immediately before the transfer Mr. Bourdeaux's health began to fail; and, though nominally in the Postal Service, he really performed but little duty since April, 1889. He was of a very genial disposition, with excellent conversational ability, and his general cheerfulness did so much to relieve the monotony of weather-bound cable operations that his absence will be exceptionally felt. He leaves a widow and 14 children.

### ELECTRICAL SECTION, LONDON CHAMBER OF COMMERCE.

THE river excursion of this section of the London Chamber of Commerce took place last Saturday under somewhat unfavourable conditions. The night previous had been very stormy, and the wind and rain were still in evidence on the river, as in London, when the time for the start arrived. The applications for tickets originally numbered 55, but owing to some delay in settling the programme, &c., that number dwindled down to 44, and of these, only 22 put in an appearance at Windsor, from whence the electric launch was to take them to Henley. Some little surprise was felt when it was found that neither Mr. Trotter, who had been responsible for some of the arrangements, nor Mr. Kenric Murray, whose name had appeared to some of the notices issued, was present when the last trains arrived respectively from Paddington and Waterloo; but this surprise became as nothing when it was found that the General Electric Power and Traction Company's electric launch, the *Viscountess Bury*, which had been engaged for the occasion, was not forthcoming. Some petty excuse was suggested about a dynamo (presumably at the charging station) having broken down, but the *Ray Mead*, which had a party on board, seemed not to have been affected by the same disaster. Supposing, however, that the charging dynamo had broken down, there are more charging stations and electric launches on the river, and we cannot think why such an unfortunate *contretemps* was allowed to arise.

Well, the electric *Viscountess* not being available, a steam *Duchess* was engaged, which, by the way, could have accommodated conveniently no more than the small contingent which arrived, and the journey was made. The luncheon provided for 44 proved amply sufficient for 22; the weather cleared as the day advanced; and Major Flood Page, who kindly took charge in the absence of Mr. Trotter, with much geniality and tact managed to convert a threatened *fiasco* into a fairly enjoyable excursion. When the Section again attempts an electric launch excursion we would suggest hiring the *Volta*, whose owners have never yet found it necessary to disappoint those who engage her.

### TELEGRAPH CLERKS AND THEIR GRIEVANCES.

THOUGH it may be urged, by those who regard them with perhaps unsympathetic feelings, that the present "agitations" amongst various sections of the working community are of "mushroom growth," still this cannot be said of the discontent and agitation existing in the Postal Telegraph service.

In Parliament, where the agitators have many friends, through the press, through the medium of public meetings, and by numerous petitions, the grievances peculiar to the telegraph clerks in the service of the Crown have

been again and again brought before the notice of the public, and since 1880-1 from time to time, at varying intervals, their claims to a better status have been made with a persistence, and, it must be added, a forbearance, which have not been without their effect on public opinion; and as a series of recent incidents appear to have somewhat accentuated their case, some reference to it here may prove of interest to our readers.

As is well known, a measure of reform was brought out in 1881 by the late Prof. Fawcett, who was at that time Postmaster-General. The great political economist had gone exhaustively into the varied features of telegraph clerks' grievances. Deputations of representatives—metropolitan and provincial—were closely and critically examined by him in the presence of a number of surveyors, postmasters, and other "permanent officials." A vast amount of evidence was placed before him, and, judging from what Mr. Fawcett afterwards said, was also accepted by him.

It is interesting to know that, though blind, Mr. Fawcett had such a faculty of recognising individuality of sound, that he was able on hearing a voice a second time to address the speaker by name, though the name had been but once mentioned.

It is also recorded that the permanent officials mentioned above did not receive these deputations with much show of favour or sympathy. To return, Mr. Fawcett declared that great hardships and grievances undoubtedly existed, and, in the result, the Fawcett scheme was the panacea which was to banish the ills of the whole service.

It would appear that it has failed to do so, and the lamented death of Prof. Fawcett may have curtailed the extent and scope contemplated for it by its author.

Sir John Puleston, M.P., it may be remembered, in addressing a crowded meeting of telegraph clerks at the Forester's Hall, London, last year, told them that when he congratulated Mr. Fawcett in 1881 on his efforts to do justice to telegraph clerks, the Postmaster-General replied, "Yes; but it is not enough." The effect of this remark on Sir John's audience may be imagined better than described; but it tends to show that the author of the Fawcett scheme did not look upon his labours as wholly accomplished, and his remark to Sir John Puleston may be said to be a very strong confirmatory point in the matter of the genuineness of the present grievances.

Now, as in 1881, the causes of dissatisfaction are attributed to:—

1. Inadequacy of pay.
2. Classification causing stagnation in, and irregularity of, promotion.
3. Deduction of pay during absence on sick-leave.
4. Undue length of duty.
5. Insufficient annual leave.
6. Inadequate pay for overtime.
7. Vexatious and unfair duties.
8. The performance by senior clerks of assistant superintendents' duties without extra remuneration or privileges.
9. Attendance on Bank Holidays without extra remuneration.
10. Lack of superior appointments.

Into each of these heads the telegraph clerks throughout the service have gone very fully in their petitions, and that they have made out a case may be inferred from the fact that the Postmaster-General, having received a report from a departmental committee, has made fresh recommendations to the Treasury, and their advent is awaited, we can fully believe, with feverish and pent-up anxiety. Unfortunately the Treasury enjoys, rightly or wrongly, the reputation of being a sort of monetary "Court of Chancery," whose deliberations are uncertain, occasionally arbitrary, and frequently protracted to an almost unbearable point.

Touching generally upon points into which we cannot enter in detail, some concessions have been made in the matter of sick pay, and if it is granted to a few there can be no good or just reason for withholding it from the remainder, irrespective of class.

We may say that the granting of Bank Holidays is not insisted on, and the telegraph clerks are not unreasonable in asking for overtime for such days.

Inadequacy of pay and classification, which latter gives rise to many anomalies in the matter of position, salary and service, are evidently the two standard grievances throughout the service. From what we have read, and from what we know of the service, it seems possible that the maxima which clerks might reasonably expect to reach will never be attained, and the question must surely present itself to the thinking mind whether it were not better to abolish the barriers at several stages, and allow a steady and gradual rise through the grades to a maximum, which, after all, even under the most favourable circumstances, would not be reached until after upwards of 25 years' service. It is no satisfaction to a man who has spent his years in faithful and meritorious service to be told, as has been done in our public departments, that "he is very unlucky," "he was just in an unfortunate position," or that he is "worthy of every encouragement," when none is forthcoming. The reward of faithful service lies chiefly in steady promotion, and before leaving the general question of pay, we may point out one very striking disparity which appears to be apparently unexplained. Take the case of senior clerks—previous to 1881, the difference between the maximum of a senior clerk in London and that of an assistant superintendent was £60. In 1881 the difference was increased to £80. In 1889 we find that the difference reaches no less a sum than £110. No sufficient reason is given for this remarkable expansion on the one hand, and the standstill on the other. Other cases could be shown, into other points want of space prevents us going. We know that the position of Mr. Raikes is one of difficulty and responsibility. He has expressed a becoming desire to be "just before he is generous." It may be that the events of the next week or so will prove that he can be both, and yet we do not know that the telegraph clerks are asking for more than simple justice. We venture to assert that the nation does not wish to see any of its public servants in positions in which they fail to receive adequate remuneration and consideration from the nation's purse.

Science, ever marching onward, leaves behind it new theories, new systems, and new labours. To electrical science this truism peculiarly applies, and it cannot be said that even now a telegraph clerk has nothing more to learn. The service, indeed, ever moves on with the sciences. We need not dwell on the specially-trained intellectual force that has to deal with current topics of all kinds, from the reports of great Parliamentary or scientific debates down to the humblest of telegraphic business. In all departments it may confidently be said that a high standard is maintained. It is but right to expect that those connected with the greatest telegraphic system in the world should be in positions more than one degree removed from the fringe of poverty; that they should feel that they are cared for by an appreciative administration, and it is to be hoped that the Postmaster-General will see that no unnecessary time is lost in readjusting the balance of justice.

In conclusion, we may say with Sir John Puleston that the claims put forward by these public servants are indeed moderate, and we hope that the tension at present existing may be carefully, manfully, and wisely controlled by the men, and that their conduct may be marked by extreme forbearance and a due consideration of the public service, as, we also trust, their claims will meet with a speedy, just, and liberal recognition at the hands of their professed friend the Postmaster-General.

**The Use of the Sprague Motor.**—On account of the efficient regulation of the Sprague electric motors many printing firms in the States have adopted it in preference to any other form of power. The Sprague Company has now about 20 motors in use in Boston for operating presses alone, while the total number in that city is about 200.

## NOTES.

**The Electric Light in Warfare.**—Some important electric light experiments were carried out in connection with the mobilisation of the Needles sub-section of the fortress of Portsmouth. The various forts and batteries which guard the western entrance to the Solent were supplied with powerful search lights, which have been fully engaged at night for the purpose of discovering the movements of the *Rattlesnake*, *Hecla* and other of Her Majesty's ships which were manœuvring in the vicinity.

**Proposed Electric Lighting at Exmouth.**—The Devon Electric Light and Power Supply Company, Limited, will apply for a provisional order for the lighting of the Exmouth Local Board district.

**Proposed Electric Lighting at Guildford.**—The House to House Electricity Company, Limited, has given notice of intention to apply to the Board of Trade for a provisional order, authorising them to supply electricity for public and private purposes in Guildford.

**Electric Lighting at Bromley.**—Messrs. Laing, Wharton & Down have given notice to the Bromley Local Board that they intend applying for a provisional order for the lighting of the town by electricity.

**Halifax and Bermudas Cable.**—The final splice was made on Monday last, and the cable will shortly be opened for the transmission of messages.

**Barnet Lighting.**—At the close of the meeting of the Barnet Local Board last week, Mr. James handed in the following notice of motion: "That the clerk be instructed to give notice to Mr. Joel and 'The Electric Light Company,' that this board will oppose any application by both, or either of them, for any provisional order or license extending beyond the term of Mr. Joel's contract with the board."

**The City Lighting.**—Says the *City Press*:—"When will the City be lit by electricity? The Commissioners of Sewers seem to be in no particular hurry, nor do the contractors for the two districts already apportioned. The third district will probably be kept in darkness to see how the other two get on. One contractor neglects to provide the necessary guarantee, and the other is supposed to be promoting a company to carry out the work."

**The International Exhibition of Mining and Metallurgy.**—The above exhibition will be opened next Thursday at the Crystal Palace. Among the probable English exhibitors may be mentioned Messrs. Davey, Paxman & Co., Richard Hornsby and Sons, Limited, Hathorn, Davey & Co., the Delta Metal Company, Limited, Sphincter Grip and Armoured Hose Company, Limited, W. H. Wilcox & Co., the Sandycroft Foundry and Engine Works Company, Limited, T. B. Jordan and Son, the Britannia Company, of Colchester, &c. Electrical firms will be conspicuous by their absence, Messrs. Woodhouse and Rawson United, Limited, being, as yet, the only intending exhibitors. Many South African and foreign silver, lead, gold, and copper mining companies will make a display of their products.

**Electric Stations and the Public Health.**—The Sanitary Council, Paris (Seine Department), has been requested to report upon the advisability of including electric stations in the list of *établissements insalubres*, by reason of the noise, trepidations, and smoke caused by them, and which have been bitterly complained of. In the last three years about 30 important electric stations have been erected in central positions.

**Execution of Kemmler.**—The latest report states definitely that Kemmler is to be executed by electricity.

**Small Capitals.**—The *Financial Times*, noticing the small capital (£100) of the Weston-super-Mare Electricity Supply Company and the Bristol Company, asks if the registrations emanate from the local gas companies for the purpose of protecting their interests. Our contemporary may be reassured on the point, and we recommend a closer scrutiny of the names of the promoters.

**Telephonic Communication Between Manchester and Dudley.**—The National Telephone Company notifies that communication has been established between Manchester and Dudley, and will henceforth be available.

**Cathcart and Peto.**—We learn that this firm has acquired the business and works of the Vulcan Manufacturing Company, makers of electric bells, indicators, &c., Roccliffe Street, Islington. The business will be carried on at the same address and under the same title as hitherto.

**The Elmore Wire Company.**—We hear that this company has contracts to take the whole of its output of copper spirals for the year 1891 at very remunerative prices. Mr. Elmore's latest invention in connection with the manufacture of mandrils for his process, we are assured is now a practical success. This is of great importance to the company, inasmuch as it has experienced the greatest difficulty in obtaining suitable mandrils.

**Electric Lighting at Thetford.**—The committee of the Mechanics' Institute has decided to fix the electric light throughout the building.

**F. H. Royce and Company.**—A revised price list of dynamos, dated 1st July, is being issued by Messrs. F. H. Royce & Co., of Manchester.

**Platinum.**—The difficulties attendant on the electro-deposition of platinum are well known, and the paper by Mr. Wahl, which we publish on another page, will prove a valuable addition to the literature, none too extensive, which exists on the topic. It is to be hoped that the day is not far distant when the application of platinum to plating purposes will become an industry of great importance, and *apropos* of this it may not be generally known that the price of this metal is about three times as much as was the case not long ago. One company, however, which uses this indispensable article in the manufacture of incandescent lamps was fortunate enough, when the market price was low, to lay in a stock sufficient to last for the next four years; a capital instance of the far sightedness of its well-known secretary.

**The Cost of Electric Traction.**—The General Electric Power and Traction Company will probably think it advantageous to give a reply to the assertions made by Mr. Willbond, during the discussion on electric tramways at the annual meeting of the Tramways Institute of Great Britain. To convert an assumed profit of £70 into an alleged loss of over £100 requires explanation, and we trust that the company is in a position to offer a satisfactory answer to Mr. Willbond's statements.

**Personal.**—Mr. A. P. Trotter has been appointed editor of the *Electrician*. We congratulate the proprietors of this journal upon such an acquisition to their literary staff.

**Birkenhead Electric Lighting Bill.**—This Bill, in an amended form, passed the Committee of the House of Commons on the 3rd ult.

**The Telephone in Italy.**—The Minister of Posts and Telegraphs contemplates the establishment of a system of telephonic communication all over the peninsula.

**Extension of the Telephone in Hampshire.**—Southampton and Bournemouth were connected last week by telephone.

**A Question of Wrongful Dismissal.**—In the Birmingham County Court, on Tuesday, Messrs. Snell and Prideaa, electrical engineers, Holloway Head, sued Thomas Lynch Hemming, electrical engineer, 94, Nursery Terrace, Hunter's Road, Handsworth, for £50 damages, for breach of contract to serve them for three years from 25th June, 1888. The defendant set up a counter claim for £249 as damages for wrongful dismissal in having refused to allow him to fulfill his agreement, and for the detention of certain tools and utensils. The case was tried by a jury. The jury gave a verdict for the plaintiffs for £30, and for the defendant for 7s. 6d. on the counter-claim.

**A New Insulator.**—The *Bulletin International de l'Electricité* mentions a new type of Berthoud-Borel cable, which is said to possess the property of insulation in a great degree. A layer of celluloid is first placed over the conductor, which is then encased in tarred hemp, over which a coating of some complex material follows. This last is said to offer a high insulation. Our contemporary is disposed to make light of the invention, seeing that celluloid possesses a high coefficient of dilatation, so that any sudden variations of temperature might occasion the loosening and destruction of the insulator, and, also, the inflammable nature of this material would have to be taken into account.

**Newspaper Enterprise.**—In consequence of the failure of the gas supply, the *Yorkshire Post* of Tuesday last week was produced entirely by the aid of wax candles. The text was written, the type set, and the paper was stereotyped and machined by the light of wax candles alone. Thursday's issue was to a large extent produced under very different conditions. The electric light was the illuminant in use from between 10 and 11 o'clock on Wednesday night. Such a rapid change from the modest wax-light to the brilliancy of electricity requires explanation. Because of the difficulty experienced on Tuesday night it was resolved on Wednesday morning by the management to introduce the electric light into the offices. The order for the installation was only given to Mr. Wilson Hartnell, electrical engineer, Leeds, at 11 o'clock on Wednesday morning, and it was at work at a few minutes to 11 at night. The power for driving the dynamo was, of course, already on the premises, it being derived from the engines working the printing machines. But the main shaft had to be cut for the driving pulley and a special countershaft provided, from whence the dynamo is driven, the latter running at 1,000 revolutions per minute. The installation consists of 40 lamps of 50 candle-power, and 20 lamps of 16 candle-power each, placed in the composing room, with six lamps of 100 candle-power in the machine rooms.

**Raw Hide Gear.**—In America the use of raw hide for gearing has come largely into use. It is often necessary to employ gear wheels running at a high rate of speed, and the wear which takes place, together with the accompanying noise, makes their use objectionable. Many attempts have been made to overcome these defects, and the patented solid raw-hide gears made by the New Process Raw Hide Company, of Syracuse, N.Y., have met with remarkable success. In the manufacture of the raw-hide, great pressure is applied, and all superfluous matter eliminated, leaving the same extremely light, and making it the strongest material for its weight known. The blanks are first cut, then a number laid together, and the teeth afterwards shaped out. The wheels so made have come into extensive use on electric cars, where their silent and even operation has added much to the comfort afforded by these cars. These gears may be run together or against metal gears, and require no lubrication. They are not only remarkably durable in themselves, but it is claimed that the life of large iron gears is longer, used in connection with them, than when running with metal pinions.

**The Western Gas Association of America.**—The Western Gas Association held its 13th annual meeting at St. Louis on May 21-23. In the course of his address, Vice-President C. R. Faben, Jr., of Toledo, O., said:—The electric light as a competitor to gas, for purposes of light, presents a solid front. How very profitable to investors these electrical undertakings may be, I question. From statements recently made I find that out of about 100 electric lighting companies in Massachusetts, only 15 declared dividends in the past year. Of these 15 companies 10 declared dividends of from 1 to 6 per cent., and only 5 declared dividends above 6 per cent. Leaving out the Boston companies, which by reason of the extent and value of their territory enjoy a greater demand for their light than exists in smaller places, the average of dividends paid by the electric light companies in the State, who paid dividends at all, has been only 4.9 per cent. Another fact in this connection is that no fund has been created by these several electric light companies to compensate for wear and tear. No depreciation has been charged off. The usual and necessary repair is supposed to represent all of the depreciations, so that the dividends paid are virtually taken from the plant itself or its value. Electric light companies are opposed to having any depreciation charged off other than the cost of repairs and renewals actually made.

**Wire Calculator.**—One of the most important problems to be solved by the practical wire man is that of proportioning the size of the wire necessary to carry safely and economically the amount of current requisite of charts and tables have been prepared with a view of helping wire men in this difficulty, but these at the for a given number of incandescent lamps. With the object of meeting the demand for something which would present the advantage of enabling the wire man to obtain results with great rapidity and conveniently, E. S. Greeley & Co., of New York, have have just put on the market a little device, called by the inventors an automatic wire calculator. It consists of two discs of stiff card-board of unequal size, the smaller one being mounted in the centre of the larger, and made to revolve thereon. On the back of the larger cardboard are full directions for the use of this unique and useful tool. One is arranged for the calculation of wire for of 110 volts, and it is understood another is in preparation arranged for 55 volts.

**The Alternating System in Russia.**—It is said the alternating system will be adopted by the Russian Government for lighting the buildings of the Imperial Palace, Zarskoe-Selo.

**Brighton Lighting.**—The committee has recommended that contracts to the extent of £7,027 be entered into with Messrs. Sharp and Kent, £5,242 with the Electrical Construction Corporation, £1,140 with Messrs. Sharp and Kent, in conjunction with Messrs. Goolden & Co., and £9,737 with Callender's Company. The net outlay, exclusive of the cost of the station site, will be, assuming only two sets of accumulators to be used, £26,887; with two extra sets, £29,429.

**The Electric Light in Lancashire and Yorkshire.**—Bills to confirm provisional orders made by the Board of Trade empowering the laying down of mains for the supply of electricity in Burnley, Morecambe, Bacup, Blackburn, Accrington, Blackpool, Huddersfield, Bury, Fleetwood, Lancaster, Salford, Crompton, Oldham, and Barnsley, have been before a committee of the House of Commons and passed, there being no opposition. A clause was inserted for the protection of telegraphic and telephonic wires.

**Electric Tramway in Bremen.**—The first electric tramway in Europe on the Thomson-Houston system was opened in Bremen on the 22nd ult. Three cars are employed, and others will subsequently be added. Each car carries two 10-H.P. motors.

**Journalists Exempt from Juries in New York.**—We note the following in the last issue of our transatlantic namesake:—"At last the journalistic profession has received recognition at the hands of the New York law makers. Editors and reporters will hereafter be excused from jury duty, ranking alongside of lawyers, physicians, and clergymen." When will the same privilege be granted in all cases here?

**The Praise-All Policy.**—In a recent number of the New York *Electrical Engineer* a description of a "Method of Telephonic Transmission," devised by a Mr. W. Vogel, is given; this description states that the invention "embodies a new application of the line wire to effect an increase in the efficiency of transmission. This is accomplished by maintaining the iron or steel conductor in a magnetic state, by which the effect of the vibrating armature of the transmitting telephone is propagated magnetically as well as electrically." The idea, which is about on a par with the spiral wire craze of a few years ago, is, we regret to see, spoken of in a leading article in terms which are not condemnatory of the absurdity of the so-called invention, though it is not urged that it might be a success; nevertheless, further trials of the apparatus in practical operation are suggested. We believe that under the able hands of the late editor, the whole matter would have been treated with the ridicule it deserves; moreover, a timely word might have saved the poor deluded so-called inventor a further useless expenditure of money which perhaps he can ill afford.

**News from Abroad.**—We are seriously thinking of the advisability of sending a few sub-editors to distant parts of the world, so that they may rapidly pick up information as to what is being done in London in electrical matters. We have, though fairly prompt, never succeeded in finding the items of news as rapidly as continental and American journals, and have come to the conclusion that being on the spot is the very worst way in which to acquire knowledge. Now, we were quite unaware that the Southwark Underground Railway had been opened, but an American contemporary announces that "recently there has been opened under the Thames a new subway, consisting of two tunnels each about 11 feet in diameter, for the use of an electrical railway, and trains consisting of a locomotive and three carriages, having accommodations (*sic*) for 100 passengers, are now run at frequent intervals from King William Street in the City to the Elephant and Castle in Surrey, a distance of a mile and a-third, in about three and one-half-minutes."

## NEW COMPANIES REGISTERED.

**Wakefield City and District Omnibus Company, Limited.**—Capital £6,000, in £1 shares. Objects: To carry on in Wakefield, or within a radius of 10 miles therefrom, the business of an omnibus and tramway company in all branches, and to work by means of horse, steam, electricity, or other mechanical power. Signatories (with 5 shares each): \*H. M. Carter, J. L. Chaplin, B. Woodcock, G. F. Roberts, \*F. K. Perkin, \*W. H. Kingswell, \*T. P. Robinson, W. Watson, Hy. Bennington, E. Long, H. Rollinson, \*H. Shaw, J. J. Hillbert, H. Smith, \*J. Cardwell, J. H. Holdsworth, J. Scott, G. Webster, W. Moorhouse, \*S. Stephenson, all of Wakefield and its vicinity. The subscribers denoted by an asterisk are first directors; qualification, £20 in shares or stock; maximum remuneration, £100 per annum. Registered office, Wood Street, Wakefield. Registered 3rd inst. by F. B. Moss, Outer Temple.

**Sherrin Electric Power Generator Company, Limited.**—Capital, £100,000 in £1 shares. Objects: To adopt an unregistered agreement between John Sherrin, John Vaughan Sherrin, and H. Ferdinand Woodgate, of one part, and G. M. Canham of the other part. To carry on business as electrical, mechanical, and chemical engi-

neers and manufacturers, and as an electric light company in all branches. To manufacture and deal in apparatus, materials, and things for the generation, distribution, supply, accumulation, and employment of electricity. Signatories (with 1 share each): G. M. Canham, Park Terrace, East Twickenham; W. J. Leslie Mumford, Applegarth Road, W; G. Jackson, 39, Aspland Grove, Hackney; S. H. Barnes, 84, Crofton Road, S.E.; R. B. Storey, 4, Vicarage Gardens, Forest Gate; D. R. Crane, 3, Erlam Road, South Bermondsey; E. Price, 2, Hanklin Road, Crouch End. The signatories and vendors are to appoint the first directors; qualification, 100 shares, and for subsequent directors 200 shares; remuneration, £2,000 per annum, divisible. Registered 4th inst. by Francis and Johnson, 5, Austin Friars.

*Note.*—The company referred to in our last issue as the Henley Electricity Supply Company, Limited, should read the Hanley Electricity Supply Company, Limited.

### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Fowler, Lancaster & Co., Limited.**—The statutory return of this company, made up to the 28th ult., was filed on the 5th inst. The nominal capital is £22,000 in £10 shares. 392 shares are taken up; upon 342 of these the full amount has been called, and £5 per share upon the remaining 50 shares. The calls paid amount to £2,600, and unpaid to £1,070. Registered office, Albert Works, Graham Street, Birmingham.

**Maquay Syndicate, Limited.**—The statutory return of this company is made up to the 23rd May. The nominal capital is £12,000, in 120 shares of £100 each, but the only shares at present taken up are the seven subscribed for by the signatories to the memorandum and articles of association. Registered office, 1, Shorter's Court, Moorgate Street, E.C.

**Liverpool Silver and Copper Company, Limited** (electrical treatment of metals).—The statutory return of this company, made up to the 10th April, was filed on the 22nd May. The nominal capital is £50,000, in £10 shares; 2,500 shares are taken up, and £3 per share has been called thereupon. The calls paid amount to £7,500. Registered office, 5, Fenwich Street, Liverpool.

**Poole and White, Limited** (electricians).—The statutory return of this company, made up to the 27th ult., was filed on the 3rd inst. The nominal capital is £20,000, divided into 3,400 "A" shares of £5, and 600 "B" shares of £5 each; 970 "A" and 600 "B" shares are taken up, the latter being considered fully paid. Upon the "A" shares £2 10s. per share has been called, the calls paid amounting to £2,425.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### The India-Rubber and Gutta-Percha Company, Limited.

THE half-yearly general meeting of the company was held at Cannon Street Hotel on Thursday, the 10th inst., for the purpose of obtaining the shareholders' sanction to an interim dividend of 5 per cent., or 10s. per share (free of income tax), payable on and after the 11th inst.

The Chairman, Mr. S. W. Silver, in moving the resolution, said that a rough estimate of the amount of sales made in the past six months fully justified the payment, as the sales were in excess of those of any previous half-year, notwithstanding severe competition, and a considerable increase in the price of the raw material. The works were fairly well employed. These satisfactory results had only been attained by the closest attention and care.

Mr. Grey seconded the resolution and, referring to the recent strike at Silvertown, said that no loss had been occasioned by it, as the company had been able to execute its orders from its works in France. Had proper police measures been taken, the strike would have been prevented at the outset, instead of continuing for some twelve weeks. The loss to the workpeople had been about

£20,000, which they would have received had they continued at work. He hoped they would consider well the result of the last lesson before they struck again.

The motion was carried unanimously, and with a vote of thanks to the Board, the meeting dispersed.

#### The South of England Telephone Company.

THE report of the directors for the year ending 30th April, 1890, to be presented at the seventh ordinary general meeting to be held at Winchester House, on Friday, 18th July, at 12 o'clock, states:—The expenditure on capital account for the past year amounts to £14,116 2s. 10d., bringing the total of that account to £78,418 2s. 0d. The revenue account shows a sum of £21,549 18s. 9d. for subscriptions and rentals, and a net credit balance of £6,148 5s. 4d., making, with the sum of £627 1s. 2d. brought forward from last year, an available balance of £6,775 6s. 6d. Of this amount the sum of £1,796 14s. 7d. has been absorbed by the payment of an interim dividend on the preference shares at the rate of 6 per cent. per annum for the half-year ending 30th October, 1889. In order to strengthen the position of the company, the directors have considered it advisable to carry £1,000 to the reserve fund; and they now recommend the payment of a final dividend at the rate of 6 per cent. on the preference shares (£2,096 6s. 2d.), for the half-year ending 30th April, 1890, and the payment of a dividend of  $\frac{1}{2}$  per cent. on the ordinary shares, free of income tax (£1,500), for the year, leaving a balance of £382 5s. 9d. to be carried forward.

The completed trunk lines are as follows:—Brighton—Shoreham; Brighton—Eastbourne; Brighton—Worthing; Shoreham—Worthing; Brighton—Hurst; Brighton—Newhaven; Brighton—Rottingdean; Brighton—Lewes; Lewes—Eastbourne; Canterbury—Ramsgate; Ramsgate—Margate; Ramsgate—Sandwich; Ramsgate—Deal; Canterbury—Faversham; Canterbury—Whitstable; Canterbury—Dover; Dover—Folkestone; Chatham—Maidstone; Norwich—Great Yarmouth; Northampton—Wellingboro'; Wellingboro'—Kettering; Kettering—Rushden; Tunbridge Wells—Tonbridge.

The trunk lines in process of construction are:—Canterbury—Ashford; Faversham—Sittingbourne.

At the 30th April this year, 2,265 exchange lines and 583 private lines were completed, and 91 exchange lines and 19 private lines were in course of construction.

Telephone exchanges are now open at the following places:—Brighton, Cambridge, Canterbury, Chatham, Deal, Dover, Eastbourne, Faversham, Folkestone, Great Yarmouth, Hastings and St. Leonards, Hurst, Hythe, Ipswich, Kettering, King's Lynn, Lewes, Maidstone, Margate, Newhaven, Northampton, Norwich, Oxford, Peterborough, Ramsgate, Reading, Rottingdean, Rushden, Sandgate, Sandwich, Shoreham, Tunbridge Wells, Watford, Wellingborough, Whitstable, Worthing. Mr. D. Owen Bateson retires from the board by rotation, and, being eligible, offers himself for re-election. The shareholders' auditor, Mr. J. Weise, retires, and is eligible for re-election.

The following is a comparative statement of exchange and private line business of the company:—

		Exchange.		Private.
April 30th, 1886	...	687	...	248
April 30th, 1887	...	1,130	...	348
April 30th, 1888	...	1,521	...	386
April 30th, 1889	...	1,972	...	500
April 30th, 1890	...	2,356	...	602

**The India-Rubber Estates Company, Limited.**—The prospectus states that this company has been formed with a capital of £225,000, in 225,000 shares of £1 each, for the immediate purpose of acquiring and working a concession from the Government of the Republic of Liberia for the sole right of collecting and exporting India-rubber and gutta-percha from the republic, for the European and American markets, and with the intention of acquiring and working other valuable concessions relating to India-rubber and gutta-percha from other foreign Governments in Africa, America, Madagascar, and other parts of the world.

**The Eastern Telegraph Company, Limited.**—The directors after placing about £120,000 to reserve fund, recommend a balance dividend of 2s. 6d. per share and a bonus of 3s. per share, making a total distribution of 6 $\frac{1}{2}$  per cent. for the year ended March 31st last.

**The Allgemeine Electricitaats Gesellschaft of Berlin.**—This company will increase its capital by 3,000,000 marks. The new shares will be offered at 55 per cent. premium.

**The Telegraph Construction and Maintenance Company.**—An interim distribution of 12s. per share is announced.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending July 4th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,451.

The Great Northern Telegraph Company, Limited. The receipts for the month of June amounted to £24,600; 1st January—31st June 1890, £180,400; corresponding months 1889, £120,400; do. 1888, £132,000.

## SHARE LIST OF ELECTRICAL COMPANIES.

Present Amount Issued.	Name.	Stock or Share.	Closing Quotation. (July 3.)	Closing Quotation. (July 10.)	Business done during week ending July 10, 1890.

## WILLIAMS'S SELF-AMALGAMATING ZINC.\*

THE usual method of amalgamating battery zincs is by immersing them in a suitable acid mixture to clean their surfaces, and then spreading mercury over the surfaces which have been cleaned by the action of the acid mixture. The film of mercury on the zincs gradually disappears during the action of the cells and must be renewed by re-amalgamating or by keeping a quantity of mercury in contact with the zincs, usually in the bottom of the cells in which the zincs stand.

To avoid the trouble of frequent re-amalgamation, Dr. James B. Williams, of this city, has recently designed and patented a zinc which is self-amalgamating, and which is accomplished without removing the zincs from the cells.

The accompanying illustration gives a clear idea of the method employed by Dr. Williams as applied in the case of the plain cylindrical zinc. The cavity containing mercury, *M*, is formed entirely in the substance of the zinc. From near the bottom of the cavity a canal, *i*, runs obliquely in an upward direction, and its opening, *o*, is on a portion of the surface of the zinc which is

below the level of the battery solution. Another canal *h*, runs in an upward direction and terminates on a portion of the surface of the zinc which is outside the battery solution. The purpose of the canal, *i*, is to allow the battery solution to have access to the mercury in the bottom of the cavity, and that of the canal, *h*, to allow mercury to be poured into the cavity without removing the zinc from its cell. The cavity and its outlets are formed in the zinc during the process of casting or by drilling.

To prepare the zincs for use, they are first amalgamated in the usual manner, a quantity of mercury placed in the cavities, and the zincs placed in their cells. If the zinc bodies are used, they are first fastened to their zincs and amalgamated with them in the usual manner, and a quantity of mercury placed in their cavities, after which they are placed in their cells. The mercury is renewed from time to time, as the film of mercury on the zincs is removed during the action of the battery. The zincs continue to be self-amalgamating until the zinc is dissolved to such an extent that the cavity will no longer retain the mercury which is poured through the canal, *h*.

## NOTE ON A NEW PHOTOMETER.\*

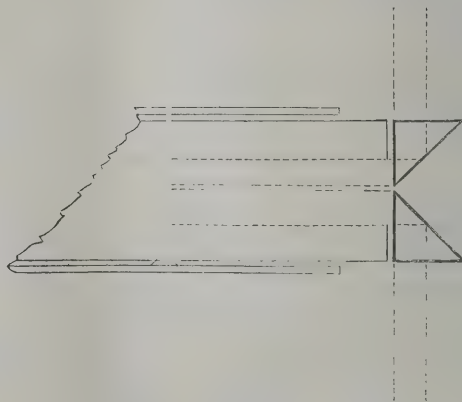

By EDWARD L. NICHOLS.

METHODS of photometry, which take no cognizance of differences of quality, are so ill adapted to the study of sources of light which differ from each other widely in temperature, that the introduction of some instrument by means of which both the character and intensity of an illuminant can be readily determined, would be a desirable adjunct to the equipment of our photometer rooms.

The instrument which it is my purpose to describe, has been designed to meet this need. Existing types of the spectrophotometer may be made to give good results, but they are expensive instruments, and so difficult to use that it is only in the hands of observers of considerable experience that accuracy is assured.

The new apparatus, the "horizontal slit" photometer, is, in point of fact, a spectrophotometer, in which the polarising device is entirely done away with. In it the extremely simple principle of the Bunsen photometer is applied successively to the various regions of the visible spectra of the source of light which are to be compared. A direct vision spectroscop of Brown-ing's form is attached to the usual car of a Bunsen photometer, from which the disc and mirrors have been removed. The optical axis of the collimator is horizontal and at right angles to the photometer bar. The slit is horizontal and lies in a straight line joining the sources of light, which are set up in the usual manner at the ends of the bar. The bar itself is preferably of considerable length—in the case of the one upon which the original instrument under consideration was mounted it was 500 c.m. long—and should be divided into 1,000 equal parts.

In front of the spectroscop slit are placed two right angled prisms of the same size, and made of the same glass (see cut). Their vertical adjacent edges bisect the slit, and light travelling from either end of the photometer bar is totally reflected by them, and enters the right and left hand end of the slit in a direction parallel to the optical axis of the collimator tube.

The two sets of rays thus gathered into the spectroscop from the lights at the end of the bar are vertically dispersed by the Amici prisms, and appear in the field of view as two vertical spectra standing side by side. Equal wave lengths are in the same horizontal line, and any desired region may be brought into the centre of the field by an angular movement of the ocular telescope. The telescope moves along the arc of a suitably divided semicircle, to which it may be clamped by means of a set screw. Wave lengths, corresponding to the various circle settings, are determined once for all by observation of the more prominent of the Fraunhofer lines.

When the instrument thus mounted is placed at the middle of the photometer bar between lamps which are identical in intensity and quality, the two spectra are of

\* Read at the Annual Meeting of the American Institute of Electrical Engineers, Boston, May 20th.

equal brightness throughout, wave length for wave length, from red to violet. If the two lamps differ in intensity but not in quality, the two spectra will differ in brightness by the same amount from end to end, and a position may be found upon the bar for which they will be identical throughout.

Under these circumstances, which are the only ones in which the Bunsen method in photometry is strictly applicable, the instrument may be used as a simple photometer, the setting for any wave length whatever giving the candle-power. For this purpose alone, viz., for the comparison of lights of similar character, the instrument offers certain manifest advantages over the various forms of the Bunsen photometer. In the course of the present paper I shall present some definite data concerning the relative sensitiveness of the two instruments when used in this way.

When the lights to be compared differ both in intensity and quality, ordinary photometric indications possess no perfectly definite significance. In this, which is the more general case, the relative brightness of the spectra of the two sources varies with the wave length. For each region of the visible spectrum, however, a position upon the photometer bar can be found at which the brightness of the two spectra in that region will be equal, and the observations thus obtained, when extended over the entire spectrum, will afford data by means of which the differences in quality of the two sources of light may be definitely expressed.

In a recent paper read before the institute (*Transactions of the American Institute of Electrical Engineers*, Vol. VI., p. 183), for a considerable range of temperature at least, the ratio between the intensities of a certain wave length of the spectrum of glowing carbon, is identical with the ratio of candle-powers, as determined by the Bunsen photometer. The wave length in question, determined from the intensity of the spectrum of incandescent lamps at various candle-powers, I had found to be approximately  $\lambda = 600$ . M. A. Crova, in an important paper since presented at the late electrical congress at Paris,\* has pointed out the importance of this method of measuring the light from sources differing in temperature. The wave length which he has indicated for this purpose is  $\lambda = 582$ , which belongs to a region lying slightly farther toward the green than the one which I had adopted.

When the wave length of this region has been established beyond question, the photometry of lights which vary in colour, will have been reduced to a definite scientific basis. Instead of attempting to use the Bunsen photometer in measurements to which it is not adapted, we shall be able to deduce the relative candle-power of two sources of light from the comparison of a single wave length, and we shall be freed from the uncertainty arising from differences of colour and from the personal errors due to the independent use of the two eyes in observation. The determination of candle-power will then be an operation of precision, even when the sources of light to be compared vary widely in temperature. It is in the opportunity of performing such observations upon the photometer bar itself, under conditions which do away with many of the sources of error inherent in the usual methods of spectrophotometry, that the chief advantage of the new photometer will be found to lie.

The following set of observations, taken with the new instrument, may serve to indicate one of the uses to which it may be put. The data are taken from an investigation now in progress in the physical laboratory of Cornell University. The object in view was to compare the spectrum of a novel type of gas burner with that of an ordinary argand burner. The two lamps were set up at the ends of a photometer bar five meters long, the bar, as already stated, being divided into 1,000 equal parts. Readings were taken at six points in the spectrum. The purposes being to express the relative brightness of the two spectra, wave length for

wave length; the intensity of that due to the argand burner was taken as unity throughout, and the brightness of each region of the spectrum of the flame under investigation was obtained in terms of that of the corresponding region of the spectrum of the argand. The results are given in Table I.

TABLE I.

Comparison of the spectrum of a Welsbach burner with that of an ordinary argand burner by means of the "horizontal-slit photometer."

Colour.	Wave length.	Light ratio, Welsbach Argand.	Probable error of a single observation.
Red ... ..	702	0.709 $\pm$ .017	2.45 per cent.

	558	1.760 $\pm$ .023	1.34 "
Green ... ..	500	2.395 $\pm$ .047	1.99 "
Blue ... ..	466	2.738 $\pm$ .036	1.30 "
Violet ... ..	439	3.090 $\pm$ .073	2.35 "
			1.76 { (Average)

From observations by Miss Ida M. Hill.

Ten observations were made in each region.

I introduce these measurements here simply as an illustration of one line of work to which the instrument under consideration is adapted. A full description of the research of which they form a part, and which covers many other questions pertaining to the very interesting class of lamps with which it deals, will doubtless be published in due time.

As will be seen from the column of probable errors the sensitiveness of the instrument is greatest in the region of the D line ( $\lambda = 589$ ), and least in the extreme red and violet, where the light intensities are small.

A set of ten determinations made by the same observer with the Bunsen photometer gave for the total light ratio of the two lamps :

$$\frac{\text{Welsbach}}{\text{Argand}} = 1.701 \pm .015$$

The probable error of a single observation in this series amounted to 0.89 per cent., a value somewhat smaller than that obtained with the new photometer in the yellow of the spectrum.

The number of observations is too small to afford a close estimate of the relative sensitiveness of the two instruments, but the results suffice to show that the "horizontal slit" photometer does not differ appreciably in accuracy from the Bunsen photometer when the latter is used in the comparison of flames of the same colour.

When it comes to the measurement of sources of light that differ widely in temperature the comparison is decidedly in favour of the "horizontal slit" photometer, the sensitiveness of which is not affected by differences of colour. The error of the Bunsen photometer in candle-power measurement of the arc light, for instance, calculated from ten observations recently made upon the same photometer bar, the reference standard being an argand gas burner, was 2.65 per cent. (probable error of a single observation), a value more than twice as large as that of the "horizontal slit" photometer.

A comparison of the performance of the new photometer with that of a polarizing spectrophotometer of the type which is commonly recognised as affording the highest degree of accuracy, is decidedly in favour of the former. Taking as a basis eight observations made by Mr. Franklin and myself in the study of a bat's-wing gas burner,\* the observations covering eight regions of the spectrum, I find the error of a single

\* M. A. Crova, *La Lumière Electrique*, Vol. XXXIII., p. 478.

\* *American Journal of Science*, Vol. 38, p. 100. See also *Transactions of the American Institute of Electrical Engineers*, Vol. 6, p. 177.

observation in the various regions to have been as follows :

TABLE II.

Probable errors of a single observation with a polarising spectrophotometer, calculated from sets of 10 observations upon various portions of the spectrum of a gas flame.

Wave lengths.		Probable error of a single observation.
753	...	7.9 per cent.
668	...	4.9 " "
608	...	4.5 " "
557	...	5.4 " "
518	...	6.4 " "
492	...	7.0 " "
468	...	3.0 " "
450	...	2.4 " "
		5.2 per cent. (average).

The measurement of a fluctuating illuminant, such as the gas flame, is a line of investigation by no means adapted to exhibit any photometric instrument at its best ; but as the errors of the horizontal-slit photometer, already given, were calculated from sets of 10 observations upon such flames, I have selected for comparison similar sets of 10 upon sources of the same character.

The averages, viz. :—

Error of horizontal-slit photometer 1.76 per cent. (average for spectrum). Error of polarising spectrophotometer 5.20 per cent. (average for spectrum) doubtless afford a fair indication of the relative performance of the two instruments in this peculiarly trying line of work.

At the last annual meeting of the Institute I had the privilege of presenting a brief study of certain personal errors pertaining to the use of the Bunsen photometer. The particular class of errors to which attention was called in that paper are undoubtedly obviated by the use of the horizontal-slit photometer ; what new ones the latter instrument may introduce remains to be determined.

## ON THE ELECTRO-DEPOSITION OF PLATINUM.\*

By WM. H. WAHL.

THE permanence and unalterability of the metal platinum—properties which make it of such inestimable value to the chemist—have likewise suggested its application as a protective covering upon the surfaces of other metals ; and, even in the early days of the art of electro-deposition, efforts to obtain a satisfactory coating of this metal were made. The failure with which these early experiments were attended served rather to stimulate than to deter subsequent investigators, and the problem has received the attention of a number of the most noted experts in the art. The results that have been accomplished cannot be said to have been entirely satisfactory—a statement which, I believe, will be fully sustained by the fact that electro-plating with platinum, on the commercial scale, is practised only to a very limited extent. When the wide field of application for platinum-plating is considered—and I need only name philosophical, engineering, surgical, dental and electrical apparatus and instruments, fire-arms, watch-cases, and jewellery, to say nothing of the host of miscellaneous articles of utility and ornament to which the metal could be advantageously applied—the conclusion is irresistible, that the processes thus far proposed for the purpose do not fully meet the requirements of practical service.

Thus far, of all the methods that have been proposed for electro-plating with platinum, three only appear

to have sufficient merit to deserve special notice ; these are :—

1. Roseleur-Lanaux method, based on the electrolysis of a solution of the double phosphate of sodium and platinum.

2. The process of the Bright Platinum Plating Company, of London, a modification of that of Roseleur, involving the introduction into the bath of certain substances, such as sodium chloride and borax, to ensure a bright deposit of the metal ; and

3. Boettger's method, founded on the electrolysis of a solution of the double chloride of ammonium and platinum in sodium citrate.

Each of these baths will yield satisfactory results for a time ; but, as I shall endeavour to show, the peculiar difficulties met with in the practice of platinum-plating render it impossible to maintain the chemical integrity of these electrolytes, and, in consequence thereof, they soon become inefficient or inoperative by reason of contamination with the secondary products formed therein.

I will endeavour in what follows to give the true explanation of the difficulties above referred to, and to indicate what, from a careful study of the subject, fortified by the results of numerous experiments, I conceive to be the only feasible method of overcoming them.

The first difficulty encountered is that of obtaining a bright, reguline and adherent deposit of the metal, in which form only it will answer the demands of practice. There is no difficulty in effecting the separation of the metal from solutions of almost any of its compounds. Zinc, iron and tin reduce it promptly by simple immersion, and this very facility of reduction is one of the reasons why, even by the method of electrolysis, the desired object is frequently accomplished only in an imperfect manner ; for the electro-plater is obliged to meet and overcome its obstinate disposition to separate from many of its compounds in the condition of platinum black, lacking coherence and adherence, and therefore entirely unsuited for his purpose.

Another and no less serious difficulty arises from the insolubility of plates or sheets of this metal as anodes, when solutions containing platinum salts are submitted to electrolysis. In electro-plating with copper, silver, gold and nickel, but little difficulty is encountered in practice on this account, since anodes of these metals are freely soluble in many solutions capable of depositing them when they are submitted to electrolysis, and the rate at which these anodes are respectively dissolved, approximates so nearly to that at which the metals are deposited upon the objects at the cathode, that the metallic strength of the electrolyte is maintained substantially uniform, and electro-plating solutions of these metals may be operated for a long time without requiring additions of metallic salts. The electro-deposition of the metals whose anodes are thus tractable is carried on industrially with success.

It results from this want of solubility of the anode that the metallic strength of the electrolyte employed is continuously being weakened, while the deposition of the metal is going on, and the conductivity of the bath is being continually modified thereby. The character of the deposited metal also is injuriously influenced by these constant alterations of condition in the bath ; and, as the rate of deposition becomes slower and slower by reason of the gradual impoverishment of the metallic strength of the solution, it will be necessary to restore it by fresh additions of metallic salt. The practice in all the processes of electro-plating with platinum employed up to the present time, save that of Boettger, is to use for this purpose the tetra-chloride of platinum. With this single exception, all the solutions for the electro-deposition of platinum thus far made known, so far as I am aware, are made by treating the chloride with compounds of the alkalies, soda, potassa, or ammonia. Of these, the phosphates and oxalates of soda, or potassa, are in greatest favour, and a number of formulæ for preparing platinum-plating baths with their aid have been described. The resulting sub-

\* Read at the Stated Meeting of the Chemical Section, Franklin Institute, May 20th, 1890.

stance is commonly a double salt, such, for example, as the double phosphate of sodium and platinum; the double oxalate of potassium and platinum, &c., contaminated, however, in each case by the chloride of the alkali employed, which is formed from the decomposition of the platinic chloride. As often as it is found necessary to strengthen the bath, fresh additions are made of platinic chloride, which, by chemical interaction with the constituents of the bath, aided by the process of electrolysis, yields more alkaline chloride; and it follows that the bath, by reason of becoming surcharged with this foreign substance, and with other secondary products of electrolytic decomposition, ceases to yield bright, reguline platinum upon the articles to be plated therewith, and must be discarded. It then becomes necessary to regain the platinum contained in the discarded bath, by one or another of several processes of reduction known to chemists. The platinum thus regained may be converted into chloride and utilised in the preparation of a fresh bath, with which the same series of operations will be repeated. Boettger purposes to maintain his bath by fresh additions of his original solutions, but it must be apparent that the continued electrolysis of such a solution as he employs must be attended with the constant accumulation therein of alkaline chlorides from the same causes as those specified above. This rapid deterioration of the baths, therefore, involve their frequent renewal at the expense of time and labour, so that, in spite of the fact that there is a wide field for its application, it is principally for this reason that the art of electro-plating with platinum on the commercial scale has thus far been practised only to a very limited extent.

It occurred to me that it might be practicable to overcome the principal difficulty here set forth. Knowing the influence of extent of surface in promoting the solubility of substances, it appeared to me at least probable that if the platinum were exhibited at the anode in the form of platinum black, or sponge, exposing thus an enormously greater number of points of attack to the electro-negative element or acid radical there set free, the result might be the solution of the platinum, and the problem of maintaining the metallic strength of the electrolyte would thus be solved. The correctness of this conjecture was verified by experiment. For this purpose a plate of porous battery carbon, previously treated with boiling hydrochloric and nitric acids, was saturated repeatedly with a solution of platinic chloride and dried. It was then introduced into a graphite crucible, finely divided carbon was packed about it, and the crucible and contents heated for about half an hour to bright redness. The carbon plate then contained within its pores platinum in a state of eminently fine division. Treatment with water, and with hydrochloric acid at boiling temperature, failed to leach out any platinum salt, showing that the previous treatment had sufficed to reduce all the platinum salt to the metallic state. The carbon plate was then suspended as the anode in moderately diluted hydrochloric acid, a platinum plate serving as the cathode. The acid bath was gently heated and a current of moderate strength was allowed to flow through it. There was a liberal evolution of hydrogen from the cathode, but little perceptible evolution from the anode. The acid solution gradually became coloured from the formation of platinic chloride, and after some time the bright surface of the cathode began to blacken and ultimately became covered with a thick coating of platinum black. It was thus demonstrated that an anode of platinum in a fine state of division is readily soluble in an electrolyte which yields chlorine at the anode when the same is electrolysed. This observation, so far as I am aware, is new. It proved, however, to have no practical value, since the solution of the anode demanded the presence of a large proportion of free acid in the plating-bath, and the use of currents of such strength as to produce invariably the deposition on the surfaces to be plated of black and non-adherent metal. Furthermore, it was found, as was to have been anticipated, that the physical condition of the anode exerted no influence whatever in the electro-

lysis of baths formed of the oxy-salts of platinum, from which the best results in electro-plating are obtained—since, in electrolysing such compounds, the acid radical separated upon the surface of the platinum black failed to exert any perceptible solvent action.

It was therefore necessary to devise some other plan for overcoming the difficulties herein described, and, after making a number of fruitless experiments, I was so fortunate as to find a plan which appears to offer a solution of the troublesome problem of electro-plating with the group of metals, whose anodes are insoluble, in a more satisfactory manner than any other that has hitherto been suggested.

The plan here referred to consists in employing platinum hydroxide for the purpose of maintaining the metallic strength of the plating bath. For this purpose, the hydroxide, which is readily soluble in alkalies and in many of the acids, may be introduced into the plating bath from time to time and dissolved therein by stirring, or it may be permitted to remain in the bath in excess, the undissolved portion remaining at the bottom of the containing vessel, or it may be suspended in a canvas bag adjacent to or surrounding the anode of carbon, according as the nature of the electrolyte may indicate one or the other method to be the preferable one. As the solutions which yield the best results in plating are those of the oxygen salts, I have found it advantageous also to prepare these directly from the hydroxide. This method, I have found, is capable of yielding a number of electrolytic baths of platinum that will maintain their metallic strength approximately unimpaired during electrolysis, and without the objectionable features of introducing into them substances that will cause them to deteriorate by the accumulation therein of injurious secondary products of decomposition, as is the case where such baths are maintained by additions of platinic chloride or alkaline chloro-platinates, as has hitherto been the invariable practice. Referring now specifically to the properties that render the platinic hydrate useful for the purposes above indicated, the following points appear to be deserving of mention.

It is readily soluble in aqueous solutions of the alkaline hydrates, and in a number of acids, mineral and vegetable. In the treatment of the platinic hydrate with aqueous solutions of the alkaline hydrates, the former plays the part of a weak acid forming compounds known as platinates, which are very soluble, and from which the platinum is not precipitated on the addition of an excess of alkali. A weak aqueous solution of sodic or potassic hydrate (but especially the last-named) will dissolve a large quantity of platinic hydrate, at the ordinary temperature, though solution takes place more freely when heat is applied. These solutions have the advantageous features of being freely conductive of electricity, and of yielding bright, reguline and adherent electro-deposits of platinum on metallic surfaces previously prepared to accept the same. Furthermore, with a current of moderate strength, the platinic hydrate only is affected, as is shown by the pronounced evolution of oxygen at the anode, and by the total absence of gas at the cathode. Also, it is manifest from the free solubility of platinic hydrate in alkaline hydrate, even in the cold, that if free platinic hydrate be present in a bath of alkaline platinate, the alkali set free in the process of electrolysis will combine with this platinic hydrate to form fresh platinate. For this purpose it will be necessary either to have present in the bath at all times a small excess of platinic hydrate which may remain upon the bottom of the containing vessel, without interference with the plating, and which may be replenished from time to time; or to introduce, at the end of the day's work, a quantity of the platinic hydrate sufficient to restore the metallic strength of the bath to normal, assisting the solution of the metallic hydrate by stirring, and, if necessary, by the application of gentle heat. As I have found that the platinate solutions act best when they contain a considerable excess of free alkaline hydrate, being more conductive of the current and yielding the platinum more freely and in the best condition, the addition of the proper quantity

of platinic hydrate at the close of the day's work in the case of a bath of considerable volume, or the addition of small quantities at intervals, in the case of a small bath, will be found to answer the desired purpose of maintaining the metallic strength of the bath approximately normal for an indefinite period. In a bath where considerable free alkali is present the platinic hydrate added, as just indicated, dissolves very freely even in the cold. The important fact is to be noticed that the alkaline platinate solutions may be maintained and operated for a long time in the manner described, since no deleterious secondary products are formed by electrolysis to vitiate and render them inoperative, as will speedily be the case where the platinic chloride is used for this purpose. The mineral acids (hydrochloric, nitric, sulphuric, and phosphoric acids) dissolved the hydroxide freely, as likewise do certain of the vegetable acids, notably oxalic acid, and form with corresponding salts of the alkalies, double salts, many of which are soluble in water. Of the salts thus capable of being formed, however, so far as I have been able to determine by experiment, only a limited number appear to be adapted to yield a deposit of bright, reguline and adherent platinum. The halogen compounds may obviously be prepared more conveniently by the direct solution of the metal in *aqua-regia* than by the method I have described, but as I have found the oxygen compounds of platinum to yield much more satisfactory results, I therefore exclude them from consideration.

Of the salts that may be formed from platinic hydrate by solution in acids (and in part by suitable combination with the corresponding alkaline compounds to form double salts), three only may be named as sufficiently useful to yield practically valuable results in plating. These are the phosphates, oxalates and acetates, of which also it is practicable to form double salts with the alkalies, soda, potassa and ammonia, which yield bright, reguline and adherent plating.

Oxalic acid, so far as I have been able to determine, of all the oxygen acids, is the best solvent of platinic hydrate, dissolving it even in the cold, but with great energy when aided by heat, and forming platinous oxalate, with evolution of carbonic anhydride. From this brownish-black or deep blue solution (according to concentration), brilliant reddish-brown scales of the salt separate abundantly and readily from the hot saturated solution. A saturated aqueous solution of the simple oxalate prepared from the hydrate, as above described, will yield bright, reguline, adherent platinum when electrolysed with a comparatively weak current, with evolution of carbonic anhydride at the anode. With a stronger current hydrogen also appears at the cathode. This bath may be maintained indefinitely at normal metallic strength by observing the precaution to add oxalic acid and platinic hydrate in small quantities from time to time; or by keeping constantly at the bottom of the bath some platinic hydrate, and adding oxalic acid in crystals or powder from time to time as may be required to keep the bath saturated; or, what is much to be preferred, making a supply of platinous oxalate from platinic hydrate in the manner previously described, and keeping an excess of this present in the bath at all times. This bath has the same advantages as are possessed by the above-described alkaline platinate baths, of being capable of indefinite maintenance at normal metallic strength, and of introducing no substances that will cause its deterioration by the formation of secondary decomposition products.

Phosphoric acid also is a solvent of platinic hydrate. A dilute aqueous solution of this acid will dissolve a small quantity of the metallic hydrate in the cold, and a much larger quantity when aided by heat. With increasing concentration, the solvent power of this acid for platinic hydrate is correspondingly increased. The resulting solution of phosphate of platinum, according to the degree of concentration, will be wine-yellow to cherry-red in colour, and with a comparatively weak current, will yield bright, reguline and adherent platinum on metallic surfaces properly prepared to accept

the same. The electrolysis of this compound, also, does not involve the formation of deleterious secondary products, the result of the operation being the separation of the metal at the cathode, and of the acid radical at the anode—and of the elements of water which are evolved as gases respectively from anode and cathode. In the operation of the bath, therefore, it will become more and more acid as the metal is withdrawn by the accumulation therein of the phosphoric acid set free at the anode. The maintenance of the metallic strength of the bath, therefore, may be effected as in the foregoing cases, by having present therein at all times a small quantity of platinic hydrate, or by the addition at the end of each day's work of the quantity of the metallic hydrate which will be required to restore the amount of metal withdrawn. This bath must be worked very acid, and the solution of the platinic hydrate to maintain the strength of the bath must be facilitated by heating, as the solvent power of phosphoric acid for platinic hydrate is much inferior to that of oxalic acid. The double phosphates of platinum with certain of the alkalies may be formed, which will be capable of yielding a deposit of bright, reguline and adherent metal, and of being maintained approximately at normal metallic strength in the same manner as I have set forth above. The best results I have obtained with the ammonio-platinic phosphate, prepared by adding to the solution of platinic hydrate in phosphoric acid sufficient aqua ammonia to cause the same to give an alkaline reaction, which point will be indicated by the formation of a grayish precipitate that will not disappear on stirring; then restoring the acidity of the solution by adding free phosphoric acid in excess, upon which the precipitate readily dissolves. The resulting solution is yellowish or brownish, and yields superb plating; though, on account of the greater difficulty of maintaining its metallic strength by the solution of the hydroxide, it is not so well adapted as the oxalate for the work of electro-deposition on the large scale. The sodio-platinic phosphate, formed in a manner precisely analogous to the ammonia compound just described, will also yield bright, reguline and adherent plating; but I have observed that the soda salt is less freely soluble than the corresponding ammonia compound, and consequently more difficult than the latter to maintain of normal metallic strength.

Platinic hydrate is only very sparingly soluble in strong acetic acid, and it is impracticable to facilitate the solution by boiling, since by persisting in this for a very short time, the hydrate is decomposed, and black platinic oxide is formed, which is quite insoluble in this menstruum. I have found, however, that an alkaline acetate bath may be prepared by the addition to the alkaline platينات above described, of as much acetic acid as may be introduced without causing the formation of a permanent precipitate. But although the appearance and quality of the plating obtained with this bath leave nothing to be desired, the bath does not meet the requirements in respect of indefinite maintenance in normal metallic strength and uniform composition. This difficulty, however, as I have observed, becomes less and less pronounced as the bath is made more strongly alkaline, when it approximates more and more closely to the alkaline platينات; for it is obvious that in the presence of a large amount of free alkali, this would unite with the acetic acid to form a simple acetate. The resulting solution would no longer contain sodio- (potassio-) platinic acetate, but sodic (potassic) acetate, sodic (potassic) platinate, and free alkali. Nevertheless, the presence of acetic acid in such alkaline bath appears favourably to influence the quality of the plating yielded, giving the deposited metal a whiteness approaching that of silver; and since, furthermore, acetic acid yields only the elements of water and volatile compounds when electrolysed, and therefore does not contaminate the electrolytic bath by forming deleterious secondary products, I find its judicious addition to the above-described alkaline platinate baths to present some advantages.

The foregoing comprise the compounds that I have found to yield the most satisfactory results in platinum

plating, and I will not tax your patience at this time by an enumeration of the results, either partially successful or wholly unsuccessful, that I have obtained with a number of differently constituted compounds of this metal.

I append directions for the preparation of the several electrolytic baths above described, and indicate what I have found to be the most favourable conditions for working them.

In conclusion, I desire to make known the fact, which was brought to my knowledge only within the past week, that my friend, Prof. Wm. L. Dudley, of Vanderbilt University, Nashville, Tenn., has independently worked out the problem of electro-plating with iridium in a manner precisely analogous to that which I have herein described with platinum. Prof. Dudley has made no publication of his research, but in a letter informs me that he employed, as long ago as 1886, the following procedure, which I quote, "a bath of the metal may be composed of either the chloride ( $\text{Ir Cl}_4$ ), the double chloride of iridium and sodium, a double sulphate of iridium-ammonium. The latter was preferred. The bath was kept saturated with metal by suspending canvas bags in the solution (either near to or around the anodes) containing the hydroxide of iridium."

*Directions for Preparing the Electro-Plating Baths.*—For the alkaline platinate bath, the following directions may suffice :—

Platinic hydrate	...	...	...	2 oz.
Caustic potassa (or soda)	...	...	...	8 oz.
Distilled water	...	...	...	1 gallon.

Dissolve one-half of the caustic potassa in a quart of distilled water; add to this the platinic hydrate in small quantity at a time, facilitating solution by stirring with a glass rod. When solution is effected, stir in the other half of alkali dissolved in a quart of water; then dilute with enough distilled water to form one gallon of solution. To hasten solution, the caustic alkali may be gently heated, but this is not necessary, as the platinic hydrate dissolves very freely. This solution should be worked with a current of about two volts, and will yield metal of an almost silvery whiteness upon polished surfaces of copper and brass, and quite freely. There should be slight, if any, perceptible evolution of hydrogen at the cathode, but a liberal evolution of oxygen at the anode. I have observed that the addition of a small proportion of acetic acid to this bath improves its operation where a heavy deposit is desired. The anode may be of platinum or carbon, and owing to the readiness with which the metal is deposited an excess of anode surface is to be avoided. Articles of steel, nickel, tin, zinc, or German silver, will be coated with black and more or less non-adherent platinum; but by giving objects of these metals a preliminary thin electro-deposit of copper in the hot cyanide bath, they may be electro-platinised in the alkaline platinate bath equally as well as copper. The bath may be worked hot or cold, but it is recommended to work it at a temperature not exceeding 100° F. It may be diluted to one-half the strength indicated in the formula, and still yield excellent results. The surface of the objects should be highly polished by buffing, or otherwise, prior to their introduction in the bath, if the resulting deposit is designed to be brilliant.

The deposition of platinum takes place promptly. In five minutes a sufficiently heavy coating will be obtained for most purposes. The deposited metal is so soft, however, that it requires to be buffed very lightly. A heavier deposit will appear gray in colour, but will accept the characteristic lustre of platinum beneath the burnisher.

The oxalate solution is prepared by dissolving one ounce of platinic hydrate in four ounces of oxalic acid, and diluting the solution to the volume of one gallon with distilled water. The solution should be kept acidified by the occasional addition of some oxalic acid. The simplest plan of using this bath, and which requires no attention to proportions, is simply to work with a saturated solution of the oxalate, keeping an

undissolved excess always present at the bottom of the vessel. An addition of a small quantity of oxalic acid now and again will be found advantageous. The double salts of oxalic acid with platinum and the alkalies may be formed by saturating the oxalate of the desired alkali, with platinic hydrate and maintaining the bath in normal metallic strength by the presence of an undissolved residuum of platinous oxalate.

The double oxalates are not so soluble in water as the simple salt. The oxalate baths, both of single and double salts, may be worked cold or hot (though not to exceed 150° F.), with a current of comparatively low pressure. The metal will deposit bright, reguline and adherent on copper and brass. Other metallic objects must receive a preliminary coppering as above. The deposited metal is dense, with a steely appearance, and can be obtained of any desired thickness.

The deposit obtained in the oxalate baths is sensibly harder than that from the alkaline platinate bath, and will bear buffing tolerably well.

The phosphate bath may be prepared by the following formula :—

Phosphoric acid, syrupy (sq. gr. 1·7)	...	...	8 oz.
Platinic hydrate	...	...	1-1½ oz.
Distilled water	...	...	1 gallon.

The acid should be moderately diluted with distilled water, and the solution of the hydrate effected at the boiling temperature. Water should be added cautiously from time to time to supply that lost by evaporation. When solution has taken place the same should be diluted with sufficient water to make the volume one gallon. The solution may be worked cold or warm to 100° F., and with a current much stronger than that required for the platinates and oxalates. The ammonio- (and sodio)- platinic phosphates may be formed from the simple phosphate by carefully neutralising the solution of the phosphate with ammonia (or soda), then adding an excess of phosphoric acid, or enough to dissolve the precipitate formed, and an additional quantity to ensure a moderate amount of free phosphoric acid in the bath. The phosphate baths will be maintained of normal strength by additions of platinic hydrate, the solutions of which will have to be assisted by heating the bath, preferably at the close of each day's work. The metal yielded by the electrolysis of these phosphate solutions is brilliant and adherent. It has the same steely appearance as that exhibited by the oxalate solutions, but to a less pronounced degree. The physical properties of the deposited metal are in other respects like those described in connection with that obtained from the oxalate baths.

## THE PROGRESS OF ELECTRICAL TRACTION.\*

By Dr. LOUIS BELL.

THE beginning of electrical traction, or rather of its possibility, dates from that magnificent discovery of the reversibility of the dynamo, a discovery that, perhaps, cannot be ascribed to any one person or to any definite year; it was in the air during the sixties, as the telephone was in the succeeding decade; but it was not until 1873, at the Vienna Exhibition, that the possibilities of this discovery were realised. Nothing came of its except occasional applications until Dr. Werner Siemens saw all the possibilities of the motor for railroad use, and in 1879 the first modern electric railroad was built at the Berlin Exhibition. Here for the first time a moving motor was supplied with power from a distant dynamo. The current was led to the motor car through a third rail and back to the ordinary track. Very shortly afterward the experiments began in this country, first, perhaps, in the hands of Mr. Field, and

\* Abstract of paper read before the Scranton Science Club America, June 19th, 1890.

almost simultaneously at the laboratory of that incorrigible inventor, Edison. Two years more saw the opening of the Siemens electric road from Lichterfelde, a suburb of Berlin, into the outskirts of the city. Unless temporarily stopped, that road, the first practical electric road in the world, is running to-day.

Given an electric motor and a car, how can they be combined? This was the first question to be raised. Where should the motor be put, and how should it be connected with the driving wheels? Almost every conceivable spot in and about a car had been tried as a place for the motor—on the platform, in the car, on top of the car and under the car, in almost any position that could be named. Not until the present method of swinging the motor from the car axle, so that the armature would be at all times equidistant from it, was devised, were thoroughly practical results secured. But the great difficulty in the way of using the electric motor is one which at first sight does not suggest itself—the high speed at which the motor ordinarily runs. It has been up to the present quite out of the question to build a light and efficient motor in which the armature should revolve at a low speed; I mean by that, 100 revolutions per minute, or something of the kind. With the ordinary motors running from 800 to 1,200 revolutions per minute, it is obviously absolutely necessary to reduce the speed by some kind of gearing in applying it to a car axle; for if this were not done the speed of the car would be preposterously great. Within the last ten years almost every known mechanical means for reducing speed has been applied to the problem; belts, chains, ropes, worm-gearing and every description of toothed gear has been pressed into service, but one after another has been discarded as impracticable, until at the present nearly all electric cars are operated by plain toothed gearing. In the existence of this lies one of the difficulties that must be overcome in the future.

The first electric road utilised the rails; but for street traffic this is inconvenient, and all sorts of overhead arrangements were schemed, experimented on and abandoned. Cars running on an overhead wire and dragged by wires from the car were and are still in use. Copper tubes slotted beneath were employed in which the car dragged along a wire brush much after the similitude of a gun cleaner. Then came every description of under running trolley from a wire broom that scraped and ground along the conductor to the present smooth running little wheel.

Then another snag was encountered. After the electric current is led to the car, how can it best be conveyed to the moving parts of the motor? The ordinary brushes such as we see on the commutators of dynamos answer the purpose admirably except for one inconvenient fact, that it is necessary to run the armature of a motor in more than one direction, as when the car is on the return trip, and the copper brushes that worked admirably well when the armature revolved with them raised a blazing protest when the armature revolved against them. If I were asked what is the most important minor improvement in electric traction, I should say unhesitatingly that it is the introduction of the carbon brush that rests quietly on the surface of contact and is quite indifferent as to the direction of rotation of the commutator beneath it. Aside from these fundamental difficulties minor ones were met at every point of the construction of an electric railroad. The trolley wire is necessarily under high tension, and only after elaborate experiments was the hard bronze wire now used found and adopted. Then this very tension brings a severe strain on the supporting poles, and all sorts of ingenious devices had to be invented to sustain and equalise it. The road that runs on your streets to-day is a result of an enormous mass of inventive ingenuity applied in directions of which it is impossible in a limited time to give any adequate idea. That the success which has been attained is so great is a standing monument to the perseverance and genius that have produced it. The electric car of 1890 is a machine that is marvellously successful, and in view of what is being done in every succeeding week, it is not

too much to say that the horse's occupation in street car work is practically gone.

To-day the grinding gear wheels underneath the car constitute the most serious mechanical difficulty in electric railroading, and it should be the object of inventors to dispense with them if possible. It is possible, although it has not yet successfully been done, to build a motor of which the armature shall be directly upon the car axle, and that yet will operate with a fair degree of economy. This done and we should have a system of electric traction almost ideal in its simplicity; a single rotating armature grasped and centered between field magnets surrounding the axle, the current supplied to it from a movable contact, a switch to control it. That is all. And few people have any adequate idea of the mine of power that these same grinding cog wheels waste.

A question that is often asked is: Why is it necessary to put two 15 H.P. motors under a car of the same size that was previously drawn by a couple of mules. The question is a very pertinent one, though the answer is somewhat complicated. In the first place, it has been found convenient to run electrical cars at a great deal higher speed than horse cars, consequently to employ more power. In the second place, electrical roads operate with very heavy loads on grades that are tremendously severe, as steep as one foot in ten. All this requires still more power, but does not explain fully the discrepancy between these 30 H.P. motors and the aforesaid two mules. When we come to examine the power which is required to operate an electric car, taking the average of all day long, we find that the difference is not by any means so great. Somewhere from 3 to 6 H.P. is about the amount. A sudden spurt up a sharp grade will perhaps require half-a-dozen times this amount; and this is not disadvantageous, for a motor, like a mule, can, we see, pull very hard when it becomes necessary. But let us turn a little to experiments made with the view of answering the question I have raised. Most of our present electric cars have two motors, each with its appropriate set of gears, and it is an unfortunate fact that these two do not always pull together in the harmony that might be desired. There is a constant tendency for one or the other of them to do more than its share of the work, and, aside from this, the two sets of gears consume an outrageous amount of power, which, it should be remembered, does not go into any useful work but simply tends to heat and wear out the running parts. Experiments tried last winter in Colorado show the facts of the case very beautifully. A five-ton car operated with both motors at an approximate speed of 12 miles per hour required something like 6 H.P.; using only one motor, the horse-power required was reduced to five for about the same speed; and finally, removing the pinion from one of the armatures, so that the car was operated by one motor and only one set of gears, the power was reduced to something like  $3\frac{1}{2}$ , which, considering the load and the speed, is not at all too high. A pull of something like 20 pounds per ton is required on ordinary tracks; that is, the motors in this case were pulling 100 pounds at the rate of 12 miles per hour, which, reduced to foot pounds and then to horse-power, becomes about 3, which gives the motor that actually exerted about  $3\frac{1}{2}$  horse-power a very reasonable degree of efficiency. So the cost would not be at all bad with one motor either on the axle or simply geared. It is pretty clear that there is a disadvantage in the use of two motors except in so far as it is convenient to drive both axles for ease of ascending grades, and it is no less evident that a considerable power can easily be lost in gearings.

The possibilities of electric traction are by no means exhausted in its application to street cars. I do not hesitate to say—and I say it deliberately—that to operate an ordinary railroad train by an electric locomotive is a far simpler problem, electrically and mechanically, than the operation of street cars here on the streets. The slow speed necessary for street cars is, as I have already said, a disadvantage in that it compels us to gear down the motor. In running at railway speed no such difficulty is encountered, for the four or

five hundred revolutions per minute made by the drivers of an express locomotive is just about the proper speed at which an electric motor of corresponding power could be advantageously run. We should then be enabled to dispense entirely with the obnoxious gearing and to put directly upon the axle of the driving wheels an armature big enough and powerful enough to generate the required speed. Nor is there any practical difficulty in building motors big enough to do the work. There are plenty of 100 H.P. dynamos now running, and the increase of size sufficient to duplicate the power of a locomotive is the simplest sort of mechanical operation. I do not think there is a prominent electrical company to-day that would hesitate to take an order for a 500 H.P. machine and guarantee its performance. I certainly know of several that would be glad of the chance and would accomplish the task successfully.

There is no sort of difficulty in conveying the current to one of these big motors moving at railway speeds, for it has been established by experiment that the method of running contacts such as is in general use will work admirably up to the speed of 130 miles per hour, at which speed an electric car of respectable dimensions has been actually operated. The question, then, of using the electric motor for railway work is not a question of mechanical or electrical difficulties but of economy. It is worth while noticing that in an electric locomotive the big machines can be given an amount of care quite impossible on our street cars, for the good reason that while the street car motor is exposed to the wet and dust and dirt to an enormous extent, in an electric locomotive the whole can be boxed up inside of a clean car and given practically as careful attention by the engineer as is now possible in a dynamo operated in a central station.

Now as to the question of economy. The steam locomotive, in its present stage of development, is a remarkably successful machine. Nevertheless, it does consume more coal proportionately than is used, for instance, in the engines of a big steamship like the *Umbria* or the *City of Paris*. It burns, in fact, between two and three times as much coal per horse-power of output. This is not due to any radical defects in the locomotive, which, all things considered, is a good and economical machine, but arises from the fact that the huge engines of the transatlantic liners are condensing engines, nearly always triple expansion, while the locomotive is a simple engine of a class that has been generally abandoned for steamship use. The principal advantage that we should gain by using large electric motors supplied from a central station instead of the present steam locomotives would be a much more economical use of coal. It is safe to say that the consumption of fuel for a given number of horse-power produced by big engines in an electric station could be reduced to less than half what is now used to supply a similar amount of power in the locomotive. To offset this advantage there is the necessary loss of power in conveying the current generated to the running motor. If the length of line to be operated from a single station is great, this loss may be considerable; but it is unquestionably smaller than the gain to be made in the way I have suggested. Beside this, the electric locomotive does not have to drag around its supply of coal and water.

There is, too, a magnificent possibility of economy in the use of water power. Very many of our railroad lines follow the course of some river, winding in and out along a valley; frequently there would be an abundant supply of water-power near at hand, and under such circumstances the cost of operation for an electric road would become enormously less than for the same line operated by steam. Of course, this is under favourable circumstances, and therefore we should not lay too much stress upon it; but I think it is clear to any one who is familiar with the operation of big condensing engines that their advantage in economy over a locomotive is so great as to make it worth while to distribute the power from them, even at a considerable loss. The amount of copper line wire

necessary for such distribution is not at all unreasonably great; no greater, in fact, than the amount now used in trunk lines for long distance telephony; and there is every reason to believe that, taking into consideration all these things, an ordinary railroad could be operated by electricity at a cost less, or at least no greater, than is now incurred.

As the speed to be attained rises, electric power gains over its competitor; for a high-speed locomotive must carry an enormous amount of coal and have a boiler of prodigious capacity; while inasmuch as we do not have to move the fuel or boilers of a central station, their size is a matter of indifference. The speeds that are reached now with locomotives can be duplicated with motors without difficulty. I believe the present record for locomotive speed is 87 miles per hour, made this year on the Philadelphia and Reading Road, while last year, as I just mentioned, an electric car, small, to be sure, but at the same time running under some disadvantages as regards track, attained a speed of more than two miles per minute. In fact, economy aside, I do not see that we can set any limit to the running speed of a motor except that imposed by adhesion, the strength of the steel in the flying drivers to withstand the centrifugal force and the conditions necessarily imposed on the strength and smoothness of the track.

But this aside, let us cast a prophetic glance forward to the electric express train of the future. It may consist of a motor car, very likely pointed at the front to lessen the resistance of the air to its swift passage, and containing one or more powerful motors directly on the axis of its drivers and aggregating perhaps 1,000 H.P. as a nominal output. Following it the customary vestibuled procession of baggage cars, day coaches and sleepers of the ordinary size and number. Its only lights by night will be incandescent lamps; its only means of heating electric heaters distributed through the train; 10 or 15 extra H.P. are enough to furnish an adequate supply of heat. The track over which this train will run must be straight and smooth, not at all a marvellous track, but only such a one as the great English trunk lines possess to-day. A third rail or a strong bronze wire above will convey the current to the motors, and power for it all will be supplied by a series of stations perhaps 20 or 30 miles apart along the line. The train will start smoothly into motion, fly along the track at the highest rate of speed that is found practicable, and stop quickly and easily by applying its electric brakes. The system of distributing power can be easily converted into an automatic block system that will secure beautiful control of the trains and almost absolute immunity from collisions.

Of the possible speed to be reached I will not attempt to say much. I do not think, however, that 100 miles an hour is at all out of the question, for, as we have seen, nearly 90 miles an hour has already been made, and more than 80 is made for short distance by some of the regular express trains between New York and Philadelphia. But consider even what 100 miles an hour means: starting from New York, Philadelphia before breakfast; going northward, Boston an easy morning's run, and finally, perhaps, Chicago a night's trip. All this may sound somewhat fantastic to those of you who have not followed the electrical progress of the last year; but such developments are not only possible but probable. It is not so much a question of whether it can be done, as who will be the first to accomplish it. It may not be for a decade, but unless some strange series of fatalities shall intervene, I see no reason why many of this audience should not take frequent rides on just such a train as I have endeavoured to describe. The first attempt will surely be made ere long, and in the swift progress of electrical matters that first experiment, whether it should fail or not, will surely be followed with ultimate success. Ten years has seen the electric road pass from a plaything at which scoffers turned up their sceptical noses to an everyday necessity. Ten years more will see it pass from the street car of to-day to—who knows what?

10100. "Improvements in and relating to electrical indicators." A. M. FLACK. Dated June 30.

10122. "Improvements in and relating to heating apparatus for use on electric railways." M. W. DEWEY. Dated June 30.

10123. "Improvements relating to welding, soldering, and otherwise working metals by electricity." M. W. DEWEY. Dated June 30. (Complete.) [Date applied for under Patents Act, 1883, Sec. 103, 11th December, 1889, being date of application in United States.]

10124. "Improvements in electric heating apparatus." M. W. DEWEY. Dated June 30. (Complete.)

## ABSTRACTS

## OF PUBLISHED SPECIFICATIONS, 1889

6569. "Improvements in dynamo-electric generators and motors." G. E. DOERMAN. Dated April 17. 8d. A dynamo-electric generator or motor made according to the invention consists of a cast iron tube, cast in halves, each half being bolted to the other half by means of lugs or flanges cast on the exterior of said half tubes, on the interior of each half tube and centrally located a pole piece being cast, and on the ends of each half tube a bracket or plate being cast, which may partially or completely enclose the ends of its half tube, said brackets containing half of a boss, which when the two half tubes are bolted together is bored out, at the same time or at the same setting at which the pole pieces are bored out, thus ensuring centrality of an armature to be supported between the pole pieces, the shaft of said armature being supported in journals or bushes fixed in aforesaid bosses. Around the pole pieces within said cast iron half tubes are placed exciting coils previously wound and taped, and afterwards bent or compressed in a mould or otherwise to exactly fit the curvature of the interior of the cast iron half tubes around said pole pieces, the coils being made in one, or, for convenience

in bending or compressing, in two or more sections, and one or more sections may be larger than the other section or sections in the same coil, the coils thus made as nearly as possible, except where the pole pieces are situated, filling the annular space formed between the armature and cast iron tubes when the machine is put together. 6 claims.

## CORRESPONDENCE.

## Resistance Measurements.

Under the heading of "The Accurate Measurement of Low Resistances," Mr. Eden puts forth the principle of shunting a resistance to obtain a more accurate adjustment than it is possible to obtain by means of direct alterations in the series resistance of the arm of the Wheatstone bridge as arranged. I do not remember to have seen the method described before in exactly the same manner as in the article above mentioned, but I would point out that the method used by the British Association experimentalists to compare the resistance of the rotating coil used to determine the ohm, and the concrete reproduction of that value was based on a very similar arrangement of high resistance shunts to a low fixed resistance. Also a paper was read some time ago before the Physical Society, by Prof. Fleming, if I remember aright, describing a method of making standard resistance coils based on obtaining a standard nearly correct and adjusting same by means of a higher resistance in shunt. In heavy current work the principle is also very handy, as out of 10 coils in parallel one may be made slightly adjustable to correct to temperature or current density so that the resultant value of the grid resistance remains unchanged. Since the publication of the method in the last issue of the REVIEW, I have tried it in standardising resistances to carry heavy currents and have found a Thomson rheostat of 1,200<sup>ohms</sup> very handy, the resistance of its wire being taken by the P.O. bridge immediately balance has been obtained.

Charles H. Yeaman, *Electric Inspector.*

Corporation Laboratory, Liverpool,  
July 8th, 1890.

## Electric Traction.

We notice in your last issue a letter signed F. Baines, in which, when speaking of the exhibition of our new system of electric traction, at the dépôt of the West Metropolitan Tramway Company at Chiswick, last Wednesday week, he says: "I am informed by one who was present at the trial that the runs made by the open car extended over a considerable length of track, viz., about 25 yards." On the faith of his informant's statement he then goes on to speak of the demonstration as purely a laboratory experiment, &c.

We think it right to inform the public through your columns that the line on which our new system is in operation at Chiswick, and over which the car was run on the occasion in question, is 75 yards in length. It is as long as the space available for it in the dépôt, and so far as demonstrating the efficiency of the system and indicating the speed that can be obtained, it is as good as a line a mile long. We shall be happy to invite Mr. Baines to come to Chiswick and see for himself.

For the LINEE F. ELECTRIC TRACTION AND LIGHTING  
SYNDICATE, LIMITED.

Alfred E. Stove, *Secretary.*

July 9th, 1890.

[We fail to see that a line of 75 yards in length is suitable for demonstrating either the efficiency of an electric traction system or the speed which can be obtained. Surely our correspondent cannot think that a locomotive or a steamship would be tested for efficiency or pace on a length of track like the one in question, and we fear his letter is only calculated to damn the syndicate with faint praise.—EDS. ELEC. REV.]

## STATE CONTROL.

IT was Lord Salisbury who remarked of governing bodies deputed by the State, "they begin by being enthusiastic and extravagant, and they are very apt to end in being wooden," an observation which was then, is now, and, probably, will be true for all time. At first enthusiastic, they are actively officious and dictatorial, imposing all kinds of unnecessary restrictions, and, at last, wooden, they become afflicted with official paralysis, and reach a condition of functional impotence. Early they get in front and block the path of progress; later they get in the rear, and pull from behind.

But, in spite of all, the community cries for further State remedies, and for the appointment of more governing bodies. Though every week's intelligence brings us fresh tidings of official mismanagement and departmental maladministration, though times out of number our hopes in Government schemes have been crushed and our trust in administrative projects rudely betrayed, notwithstanding the lapse of time serves but to accumulate the evidence, month after month and year after year, is the same confidence shown in the power of officialism and the same faith displayed in the omnipotence of Government. Is the system of the Government inspection of vessels shown to lead to enormous bungling, then more inspection is insisted on. "When, after long continuance of coal mine inspection, coal mine explosions keep recurring, the cry is for more coal mine inspection. When a railway accident occurs, notwithstanding the oversight of officials appointed by law to see that railways are safe, the unhesitating demand is for more such officials." If a bridge is blown down, there is expressed a wish that the Government should institute a more complete system of inspection, and so on. "Daily we castigate the political idol with a hundred pens, and daily pray to it with a thousand tongues." Always the same unwavering trust is manifested, more government we must have, and if the department fails in its duty occa-

sionally and an accident occurs, does it not make up for its neglect to some extent afterwards by—holding an enquiry!

It is vain in these days of advancing Socialism to preach against Government interference. In so doing, we are promulgating ideas opposed to the spirit of the age. According to the new lights, the time for individuation has gone by. Men are no more to struggle on their own behalf, but to give their services for the benefit of the community at large. Rewards are to be apportioned to merits as on the good old system no longer, but a condition of things exactly the reverse is to be ordained. Those, who by indomitable energy and untiring effort have succeeded in securing for themselves a share of the world's rewards, are to be mulcted of some portion by the State, that to the idle and the worthless and the undeserving may be given what they have not earned. Capital will have no rights under the new *régime*. The men who have accumulated it, those who have been self-sacrificing enough to surrender present pleasure for the sake of future enjoyment are denounced in no measured terms by the labour communists. If the new democracy is ever established, the capitalist will receive but scant consideration at its hands.

That all the great industries of our country will be controlled by the State, is included in this nineteenth century evangel. The coal mines are to be managed by Government officials. The Government must purchase the railways, and to its monopoly of telegraphy, it must add that of telephony. It is little use showing that outside the exercise of its legitimate function of protection the Government mismanages everything it touches, or in bringing evidence to show that State departments are invariably a decade behind private enterprise. It is matter of history that the Navy officials commit errors which the merchant service avoids. In taking precautions to prevent the corrosion of plates, in providing sufficient boats for saving life in case of accident, in furnishing efficient apparatus for quickly lowering boats, and in adopting a governor

to prevent the engines breaking down, they were years behind the merchant service. In refusing to carry fresh water apparatus, and in delaying the adoption of lemon juice as a cure for scurvy until forty years after a chief medical officer of the Government had given conclusive evidence of its worth, are exhibited the delays due to officialism. The use of compound engines and high pressure steam, the Government adopted long after it had been recognised as essential to economy by the mercantile marine. Nay, more, there is hardly at the present moment a British ironclad which will steam at full speed for twelve consecutive hours without something breaking down. Daily we hear of bungling at the Dockyards and of mistakes at the Horse Guards. Whether the Government builds ships or manufactures guns the work invariably costs more than if done by private contractors. If it makes weapons for soldiers' use, or coats for soldiers' backs, the same want of foresight and extravagance are manifested; and it is the same in all Government departments. Of course the Post Office will be pointed out as a Government monopoly, conducted on mercantile principles, and making a profit. But it is not proved that private enterprise would be unable to carry the work on at less cost. The Post Office progresses owing to pressure from without. It is brought into closer contact with the public than any other Government department, and though nominally under the control of officials it is virtually managed by the mercantile community. It is not allowed to become inefficient, though its conduct is by no means above reproach. A department in which the officials spend a million and a half in two years without authority is conducted on a scale of recklessness which may well excite astonishment. But it bears out Sir Charles Fox's remark—that a Government office is like an inverted filter, into which you send accounts clean to come out muddy. Business conducted on such principles would for joint stock companies mean bankruptcy, for Government departments it means but additional taxation.

The efforts of the Government to control electric lighting manifest the same blunders as do previous attempts at industrial regulation. The purposes of the legislature being avowedly to protect individual interests and secure the public safety, we have already a number of restrictions formulated by the Board of Trade, which illustrate conspicuously the arrogance of officialism, but which are quite unnecessary either for the protection of interests or the avoidance of danger. That these restrictions seriously hamper the lighting industry is apparent to all. Divided in opinion as regards all the points on which amendment is desirable engineers may be, but on this one point all are agreed, that the regulations while unnecessary, constitute an actual hindrance to progress. Acts of Parliament, Model Orders and Regulations have been multiplied, and the confusion at the moment is so great that no one knows very well where we are; a fact, the knowledge of which may have influenced Major Cardew in no small degree when preparing his recent paper for the Institution. The fact is, the Board of Trade

officials lack practical experience of the industry they endeavour to control, and a time will come sooner or later when the great mass of their regulations and provisions will be revoked, or will be set on one side, becoming of none effect. Electrical engineers know their business better than does the Board of Trade, and officials can only advance in knowledge as fast as those actually doing the work acquire the information gained from practice on a large scale. It will be found eventually that only a small amount of regulation is necessary, all save that required to enforce the due performance of the contract between undertakers and consumers, to secure the public safety and protect rival interests being consigned to the limbo of obsolete legislation. The history of electric lighting measures, when it comes to be written, will pretty much resemble the history of others. We have first the Measure, then the period during which it is discovered to be a mistake. We have next an amendment Act, followed by attempts to work under its provisions. Finally, we have the repeal succeeded in due course by another legislative experiment in the shape of a fresh measure. So it has been, so it will be. The everlasting trial and error continues, each Parliamentary session bringing new Acts, further amendments, and fresh repeals.

---

The P.O. Joke.

IN the last issue of *Engineering* there appeared an article on the electrophoscope on the lines taken up by us the week before. Not only did many of the daily newspapers extol the great invention of the day, says our contemporary, but, the editor of a technical journal, which assumes that it is in the confidence of the electrical profession, was drawn readily into the snare. It certainly will be interesting, remarks *Engineering*, to see how our contemporary will climb down; perhaps by implying that, he knew it all the time, and would not spoil the little game. We do not think it difficult to identify the journal in question, but up to now we have seen no further reference to the matter in its pages.

The Electric Tramway in Buda-Pest.

IT is gratifying to learn that this line has so far proved a great success, both from the technical and commercial point of view. Our readers will remember that the Buda-Pest electric tramway was designed and constructed by Messrs. Siemens and Halske, and it was formally opened in September, last year. During the month of April of the present year it carried 337,200 passengers, or 42,684 passengers per kilometre, the line being 7.9 kilometres in length. There were 20 motor cars in daily use, excepting on Sundays and holidays, when four additional cars were called into requisition which were attached to four of the motor cars. The city possesses a horse tramway of 45.6 kilometres length, and 329 cars, which carried in the same period 33,074 passengers per kilometre, or 9,610 less than the electric tramway. Calculating the "duty" for each vehicle, it will be found that each electric motor car carried 16,860 passengers, whereas each horse car carried only 4,584 persons in the same period. The fares on the electric tramway are considerably lower than on the other lines, yet during the month mentioned, the earnings of each electric car came to 1022.95 florins; the horse car, on the other hand, earning only 369.81

florins. These figures would show that the commercial efficiency of the electric cars is much higher than that of the horse cars, and it is explained that this is mainly due to the much greater speed (18 kilometres per hour), of the former, which more than doubles the earning capacity of the line. The proportion was even greater in May last, when 387,000 passengers were carried on the electric tramway. We have no exact figures concerning the working expenses, but we are assured that they are lowest with the electric system.

“As Old as the Hills.”  
ONE would have imagined that an esteemed contemporary, conducted in the interest of certain submarine cable companies, would have known sufficient about the testing of faulty cables to have prevented falling into the error of publishing in last week’s issue an illustrated article on “A Method of Localising Partial or Dead-earth Faults in Insulated Conductors,” as if the method described was something novel and particularly interesting. The method is as old as the hills; or, perhaps, more correctly, as venerable as insulated conductors. It would be very difficult to give an exact period to its earliest discovery; but it is ancient, very ancient. When in the old days insulated conductors in the form of core or cables were found to be faulty, this method was so simply obvious that it was used. When the core was coiled the battery wire was attached to the end and there kept as the core was run off; but in the case of the insulated wire being on a revolving drum or “swift,” there was no difficulty in making and maintaining the necessary contact. It is very interesting to observe how very frequently the electrical engineer of the present day discovers methods of doing simple things which were known years ago to the telegraph engineer. It was a pity that the method, to which we have just alluded, was not patented and brought out by some eminent firm or company.

The Directors’ Liability Bill.  
IN the House of Lords, on Tuesday, Lord Herschell moved the second reading of the Bill. He said there had been a good deal of misconception in relation to its scope and object. The Bill would not deal, and was not designed to deal, more effectually with fraud than the law at present deals with it. The purpose of the Bill was to deal with persons who make untrue statements honestly, but without reasonable ground for believing them, with a view to inducing others to invest their money, or embark in any undertaking. He admitted that some of the details of the Bill were open to criticism. It was not clear, for instance, whether promoters were within its scope, yet in many cases they were the persons whom one would really like to hit; and it was certain that persons whose names were merely mentioned in the prospectus, as the bankers who received subscriptions, or the solicitors who gave the company legal advice, ought not to be held responsible for every statement put forward by the directors. “Responsible for” were very wide, and, to his mind, objectionable words, because responsibility was a question for the law to decide. The Lord Chancellor, while sympathising with the object of the Bill, had not the slightest hesitation in inviting their lordships to reject it in its present form. Lord Bramwell presented a petition from the London Chamber of Commerce, in which the petitioners stated that they viewed the Bill with very great alarm, and expressed their firm belief that if

it passed as it at present stood, no man of means and repute would allow himself to be a director of a limited liability company. He agreed with the Lord Chancellor that if it were a question of this Bill passing as it stood he should heartily vote against it; and Lord Esher remarked that not a single line of the Bill would stand examination. Lord Herschell did not know that any legislation of the kind could safeguard reckless investors from loss. The Bill was read a second time, and referred to the Standing Committee on Law. It is almost a pity that amongst those held “responsible,” the scientific expert was not included, for many a worthless scheme has been floated purely on the strength of a gushing report from some well-known professor or expert. Our opinions on the Bill, as a whole, may be read in the REVIEW for July 4th, page 11.

Scientific Reporting.  
IT is more than probable that the report on a new incandescent lamp, to which we called attention in our last issue, did not emanate direct from the Professor who carried out the experiments, but from interested parties who placed their own construction upon the loosely tabulated figures which we have since had an opportunity of examining. Nevertheless, we feel it our duty to point out how a report, seemingly guarded, may be made to indicate almost anything that is desired, and also how careful one should be to see that the calculated results contain no errors. The new lamps, which we will still designate as those of X, were 16 in number and of five different voltages, viz.:—110, 105, 100, 92, and 80. The voltage was adjusted to give the candle-power the lamps were intended to produce, which was 16. The entire batch was then averaged, a manifestly unfair proceeding when pitting the results against 100 volt lamps of another manufacture, the watts per candle-power being given as 3·778. The Edison-Swan lamps, only four in number, were tested in the same manner, and the watts per candle-power averaged, according to the Professor’s data, 4·21. Naturally this looks somewhat uneconomical for the old lamps as compared with the new, but let us examine the tests. In the following table the working out of the watts per candle-power by the Professor appears in col. A; our own calculations in col. B.

Lamp.	Volts tested at	Ampères.	Watts.	C.P.	Watts per C.P. A.	Watts per C.P. B.
No. 1...	98·9	0·643	63·63	16	3·97	3·97
„ 2...	98·3	0·628	61·7	„	4·14	3·85
„ 3...	98·2	0·631	61·9	„	4·16	3·87
„ 4...	101·4	0·652	66·1	„	4·58	4·13
					4·21	3·95

Now 3·95 is not greatly in excess of the averaged watts per candle-power of the 16 new lamps of five distinct voltages, but if we take those of 100 volts, curiously enough, also four in number, we find the average to be 3·90. Instead, therefore, of the new filaments taking less electrical energy than the Edison-Swan, we find that they are practically alike, for naturally we must select those lamps for comparison which require approximately the same voltages to give a like illuminating power. There are other points in this report to which we could take exception, but enough has been said to show that such statements as appeared in our last issue must be taken *cum grano salis*, and we shall endeavour to keep a watchful eye on the future proceedings of the owners of X’s lamp patents.

### THE TROYES CENTRAL STATION.

WITH a flourish of trumpets the Compagnie Nationale d'Electricité (Ferranti's system) inaugurated on the 21st ult. the central station at Troyes. Mr. S. Z. de Ferranti went over from England to be present at the ceremony which was rendered rather sad by the death of an employé who was killed by a shock from a transformer which he grasped to save himself from falling down a cellar. At a meeting of the municipal council, the mayor, in reply to questions, stated that the company had strictly carried out the prefectural regulations, and that no blame was attached to them.

The station is situated in the suburb of Sainte-Savine, and the plant comprises two Babcock and Wilcox boilers, one Brasseur steam engine of 150 N.H.P., and one Ferranti dynamo giving 50 ampères at 2,400 volts. As the demand for light increases it is proposed to instal two similar groups of machines. Underground two wire conductors are employed and extend about  $4\frac{1}{2}$  miles. The cables are well insulated, and are protected by an external steel wire covering. Insulated branches are jointed to the mains, which are laid at a depth of about 20 inches in the ground. The distribution is effected at an E.M.F. of 100 volts, and transformers are erected in certain places according to the consumption; current is supplied both for public and private lighting. In the former case arc lamps of 8 ampères and 50 volts are used, and in the latter incandescent lamps, of which there are 800 already in use. Light is sold at a fixed sum per lamp hour, and each subscriber has installed a Ferranti-Borel meter modified and graduated in lamp hours. The rent for the meter varies from 1s. 3d. to 4s. 10d. per month, according to the capacity. The price per lamp hour of 10 candle is  $\frac{3}{8}$  of a penny, and for one of 16 candles about  $\frac{5}{8}$  of a penny. Those persons using the light subscribe for five years, and guarantee a minimum consumption of light amounting to 29s. per annum. The company has to pay to the town a rent of 2d. per metre of mains laid, including the return.

### THE ELECTRIC LIGHT AT THE ST. MORITZ BATHS.

THE electric illumination of watering places on the European Continent has made, of late, very satisfactory progress. The favourably known health resort, St. Moritz Baths, near Engadine, in the Canton of the Grisons, Switzerland, is about to become possessed of a very interesting installation for electric lighting.

The first step is the construction of a large central station at Silvaplana, where water power is being derived from the Julien brook, with a fall of 35 metres. From here the power for the electric lighting of the entire watering place will be conveyed over a distance of  $5\frac{1}{2}$  miles. The installation will be arranged by the machinery works of Stirnemann and Weissenbach, of Zürich, who three years ago fitted up the Hotel Kulm at the village of St. Moritz (near the St. Moritz Baths) with about 2,000 glow lamps.

The central station at Silvaplana will have, at first, a capacity of 3,000 glow lamps. For this purpose three turbines will be set up, each of 125 H.P., each of which will be directly connected with an alternating current machine, type WA<sub>6</sub>. Each of these alternating machines, at a rotation of 250 turns per minute, furnishes a primary current of 27 ampères and 3,000 volts tension, and is excited by a continuous current machine of the Ganz type,  $\Delta_2$ . The regulation is effected partly by manual rheostats (one for each alternating current and exciting machine) and there is besides an automatic current regulator with a reducer and equaliser.

The water arrangements in the mountain stream, which is very violent, will be effected on the plans of the firm Largin and Grossmann, of Lucerne. The turbines and their accompanying regulators are being furnished by the firm Rieter, of Winterthur, and the elec-

trical machinery and the transformers by the firm Ganz and Co., of Budapest.

Three prominent establishments at the St. Moritz Baths will be at once supplied with the electric light.

The Bath Saloon with 700 lamps and four arc lights.

The Hotel Victoria with 700 glow lamps and three arc lights, and

The Hotel Dulac with 938 glow lamps and seven arc lights.

In these buildings there will be set up 18 transformers, each of the capacity of 8,000 watts, which convert the primary current of 3,000 volts into a secondary current of 110 volts. Of the three alternating current machines in parallel insertion, two are to perform the normal service, whilst the third is kept in reserve.

The distance between the central station at Silvaplana and the first point of distribution (the Bath Saloon) is 4,800 metres; the total distance from the central to the most remote point to be illuminated is 5,400 metres.

With reference to the high tension prevailing in the primary leads (3,000 volts) special insulators for high tensions are being supplied by the firm Johnson and Philips, of London.

The entire installation must be complete in the spring of 1891, so that the electric light may be in action at the commencement of next year's season.

### THE ELECTRICAL CONDUCTIVITY OF AIR AND THE FORMATION OF OZONE.

MORE than a hundred years ago Van Marum observed that when an electric spark is passed through a vessel containing oxygen gas, a peculiar odour is developed and the gas becomes more chemically active; thus oxygen, which has been treated in this way, will at once tarnish the bright surface of mercury.

Nearly 60 years after this interesting discovery, namely, in 1840, Schönbein wrote calling the attention of scientists to it in Poggendorff's *Annalen der Physik und Chemie*, vol. iv., p. 616. He stated that the action of the electric spark converted the oxygen into a new body, for which he proposed the special name of ozone, a word which is derived from a Greek verb meaning "to smell."

Schönbein described many of the properties of this ozone, and, amongst them, that special property of being able to liberate iodine from potassium iodide, which has since been made the basis of a characteristic test for ozone.

Ozone is capable of effecting many remarkable oxidising reactions, and on this account has been the subject of much attention from chemists. In the early fifties it was a great *cruce*, quite a bone of contention amongst the leading chemists, who were greatly puzzled concerning its constitution; amongst others, Baumert, Williamson, Frémy, Becquerel, Marignac, De la Rive, &c., joined issue.

The exact nature of ozone was discovered by Andrews (vide *Philosophical Transactions*, 1856, p. 13). He succeeded in proving that ozone is not a compound of two or more elements, as Williamson and Baumert held, but that it is merely oxygen in an altered state, or, as chemists say, in an allotropic condition.

If a series of electric discharges be passed through dry oxygen gas, a portion of it is converted into ozone, and the change is accompanied by a diminution in bulk. Chemists explain this by assuming that three volumes of oxygen condense to form two volumes of ozone. And this theory is supported by experimental evidence, most of which has been supplied by Soret (vide *Annales de Chimie et de Physique*, series 4, vol. viii., p. 113, and *Philosophical Magazine*, series 4, vol. xxxi., p. 82; vol. xxxiv., p. 26).

Ozone can be produced in a variety of ways, thus:—  
1. It is evolved at the positive pole during the electrolytic decomposition of acidulated water.

2. It is formed by the slow oxidation of phosphorus in air.

3. It is obtained when the discharge from an electrical machine is passed through dry air, or, better still, through dry oxygen gas. The silent discharge converts a portion of the oxygen into ozone. A Siemens's induction tube is the best apparatus for this experiment.

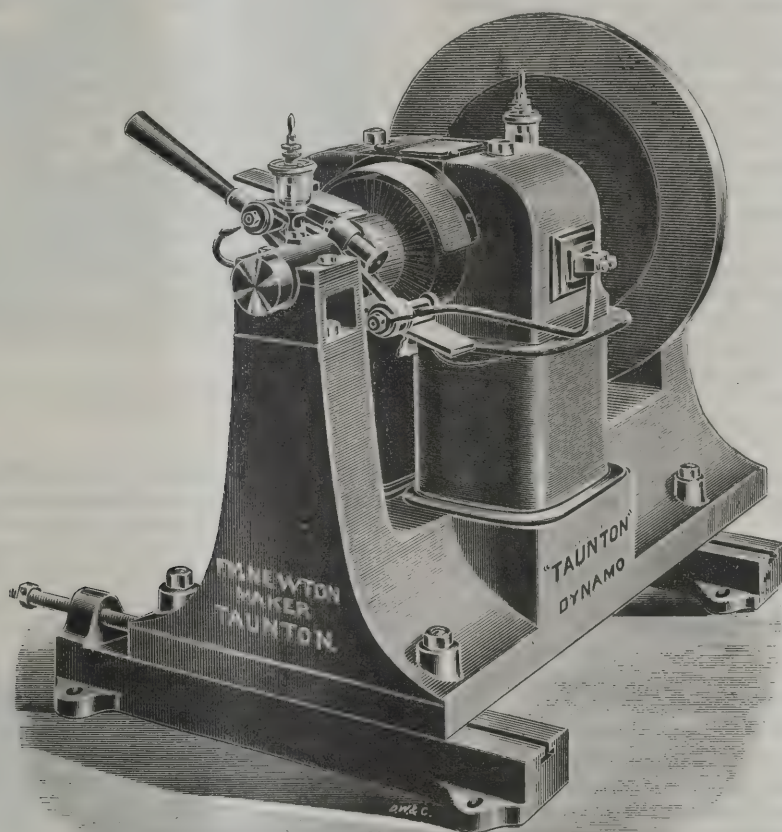

4. It is obtained by the action of a heated glass rod on a mixture of ether vapour and air contained in a beaker.

5. When a stream of air is passed on a platinum wire heated to whiteness by means of an electric current, ozone is formed.

6. It is produced during the combustion of all substances containing hydrogen in the air or in oxygen, hence it is found surrounding the flame of hydrogen, alcohol, candles, coal gas, &c.

Ozone is always found in the air which is in the

Other experiments were instituted with a view to throwing side lights upon this question, and it was shown amongst other results that the formation of solid particles of ammonium nitrite in the neighbourhood of the stick of phosphorus did not exert any appreciable effect. A curious effect was observed, namely, that the formation of ozone is hindered by the presence of oil of turpentine, and that the electrical conductivity of the air at once disappears when some of the vapour is introduced. Not only turpentine, but several of the essential oils, when acted upon by atmospheric air, transform a portion of it into ozone, and again turpentine will absorb ozone without decomposing it. These interesting results seem to indicate that there is room for still more research in this direction, which should be especially attractive to physical chemists, that is to say, to those scientists who delight in exploring the borderland between physics and chemistry.

#### THE TAUNTON DYNAMO.

vicinity of a Bunsen gas flame. Further, it is a well-known fact that air in the vicinity of such a flame possesses considerable electrical conductivity. These facts have recently attracted the attention of Messrs. J. Elster and H. Geitel, who have endeavoured to discover whether any relation exists between them. They contribute an interesting paper upon their research to the *Annalen der Physik und Chemie*, series 2, vol. xxxix., p. 321.

Suspecting that the electrical conductivity of the air in the neighbourhood of a Bunsen flame might be due to the formation of ozone, Messrs. Elster and Geitel were led to examine the electrical properties of the air enveloping a stick of moist phosphorus undergoing slow oxidation with the formation of ozone. They obtained data in their experimental investigation which enabled them to decide that the process of converting oxygen into ozone in this case, also, determined a similar assumption of electrical conductivity by the air. They were unable to demonstrate, however, that any electromotive force was connected with it.

It seems, therefore, from these experiments, that the mere presence of ozone is not in itself sufficient to impart electrical conductivity to the air, though there does seem at first sight to be some connection between the two.

THIS new pattern dynamo is of the two-pole type, built by Mr. F. M. Newton and designed by Mr. T. Hawkins. The machine has been exhibited at the Royal Show at Plymouth, where it was used to charge a set of batteries and to light Messrs. Priestman's stand being driven by one of that firm's 2-H.P. oil engines. The dynamo under consideration is shunt-wound, gives 30 amperes at 90 volts at 1,180 revolutions per minute, and runs cool on full load with an efficiency of 93 per cent.

The field magnets are made of the best wrought iron, bolted to the bed plate where the cross section has been increased, and the armature has one layer of wire wound drum fashion. There are only two turns of wire per commutator bar.

There is no lead to the brushes, and the work can be increased 50 per cent. above full load without sparking; in fact, there is no need for a rotating brush holder, and the makers intend discarding it unless specially ordered.

The machine is well designed and the bearings are long, fitted with white metal, and have sight feeding lubricators. These machines are being made in different sizes from 1 unit to 30; machines larger than this are of the four-pole type designed by Mr. Newton.

## THE ELECTRIC LIGHT AT DRURY LANE THEATRE.

### INCREASED SAFETY.

AT the annual meeting of the Drury Lane Theatre proprietors, held last Friday in the saloon building, under the presidency of Mr. Cornelius O'Dowd, Mr. C. J. Phipps, the architect, presented a report with reference to the condition of the theatre, stating that during the year there had been an installation of the electric light throughout the building.

The Chairman, in moving the adoption of the report, stated that although the institution of the electric light in the building did not bring any money into the pockets of the proprietors, they considered that it added very much to the safety of the theatre, and they therefore felt themselves justified in undertaking a moiety of the expense, the agreement with Mr. Harris being that he should pay half the expense of the electric lighting. In explaining the accounts, Mr. O'Dowd said that during the past year they had paid £1,260 for the institution of the electric light, their contract with the lessee being that he should pay half of that on the completion of the work, but as the work was not completed at the time the accounts were made up, his payment in respect of it had not yet been received, and therefore was not credited in the accounts. The proprietors would have to pay down in all about £350 more in respect to the electric light and the lessee. Mr. Harris would contribute one half. He (Mr. O'Dowd) would like to say that in addition to the establishment of the light on the stage and the auditorium, they had had it put up in other parts of the theatre.

Major Sharpe, in seconding the motion for the adoption of the report, said that he looked with much satisfaction upon the installation of the electric light, as he considered it added very much to the safety of the theatre.

The report was unanimously adopted.

## THE ZIGANG POLYPHONE.

IT is well known, writes M. Ed. Hospitalier, in *La Nature*, that the vibrating plate of a telephone may be made, under the influence of undulatory electric currents, with the necessary graduations and modulations, to reproduce all the sounds and the tones the most diverse in a gamut of the most extended scale, with only the slight and almost imperceptible alteration which is due to the fundamental sound of the vibrating plate itself. This will not be the case if we make use of the plate to modulate the current. We have already had occasion to describe M. Zigang's electric trumpet, in which a current being periodically interrupted by the vibration of the plate produces a continuous sound of peculiar tone. This electric trumpet constitutes an apparatus midway between the telephone and the electric bell, for which latter it may be substituted with advantage in a great number of cases. The first of M. Zigang's trumpets were somewhat disagreeable in sound, and the pitch was often ill defined. By rearranging the whole system with entirely metallic fittings, by suitably modifying the thickness of the plate, its diameter, peripheric mounting, the armature mass, the capacity of the resonator, and the proportions of the electro-magnet, the sound was perceptibly improved. It acquired a tone approaching to that of the hautboy, one which could be modified to considerable extent by a well arranged combination of the various organs contributing to its production. But M. Zigang aimed at something more. He aimed at transforming the monophonic trumpet, which was only capable of a single, with a perceptibly uniform, pitch, into a polyphone, or a single apparatus capable of

emitting several well defined notes. He succeeded in this by turning to advantage the connection existing between the pitch of the principal sound furnished by the vibrating plate and the diameter of the latter. The following figures illustrate the principal dispositions of the apparatus, as well as the mode of putting them in action.

The polyphone is no more than the original trumpet formed out of an electromagnet (fig. 1) mounted in front of a vibrating plate, to which a soft iron arma-

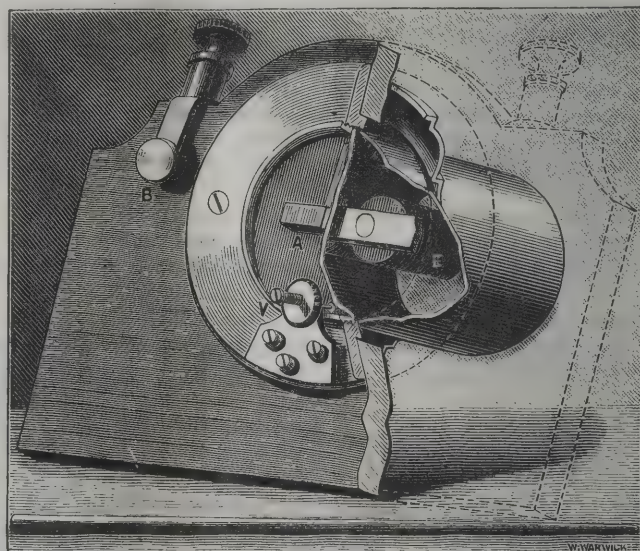

FIG. 1.—ZIGANG'S POLYPHONE.

ture, A, is attached. A platinum contact, V, closes the circuit of a battery upon the electro-magnet, and breaks it as soon as the plate is attracted, in order to establish it anew when the plate has recovered its initial position, and so on. The sound which is thus emitted is that corresponding to the natural vibration of the plate under

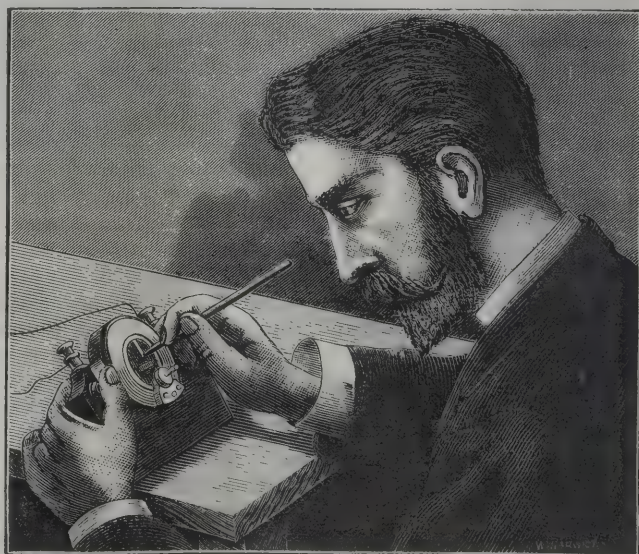

FIG. 2.—EXECUTION OF A MUSICAL AIR ON THE POLYPHONE.

the influence of the periodical creation and suppression of the currents traversing the electro-magnet. But by applying a blunt point to the plate we immobilise the entire portion of it comprised betwixt the periphery of the plate, which is fitted to the mounting, and the concentric circle which passes through the point touched. The plate thereupon emits an acute sound, which is the more acute as the point touched is nearer the centre. By touching different parts of the plate it may be made to

emit different sounds with a certain correspondence between the tones and half-tones of the chromatic scales; so that it is possible to obtain real music. This M. Zigang actually did, although the entire extent of the instrument was no greater than an octave. Each note is struck by pressing a contact button, B (fig. 1), with the left hand, whilst with the right we manœuvre the blunt point upon the surface of the plate. The connected movements are particularly facilitated by means of this instrument, upon which the inventor has already played several pieces arranged for it and for the piano. It would be possible to add to the apparatus special dispositions allowing of the easy realisation of the *forte* and *piano* notes. This might be done by introducing variable resistances into the circuit, either by varying the number of the elements by means of a commutator or by introducing into the circuit an iron-cored coil so as to modify the circuits coefficient of self-induction and thus enfeeble or enhance the intensity of the sounds at will. But it must not be lost sight of that the pitch of each fundamental sound is a function as well of the electric source and the interpolated resistances; so that the position of the contact corresponding to a note of given pitch is not always the same, but varies with the intensity of the sound obtainable, and which fact renders the performance somewhat complicated.

Nevertheless, M. Zigang's polyphone is an original and diverting instrument, and it has appeared to us worthy of being presented to our readers, if only because of its simplicity and of the experiments which it enables us to make for the purpose of imparting and demonstrating not a few of the principles of musical acoustics.

## PROF. LODGE ON THE THEORY OF THE ELECTRIC WELDING PROCESS.

By S. ALFRED VARLEY.

IN the columns of *Industries* of June 27th, there is a communication from Prof. Lodge which purports to be of the nature of a reply to recent articles of mine which have appeared in the *ELECTRICAL REVIEW*.

It is not without significance that Prof. Lodge should have preferred his comments to appear in a journal, many of whose readers will, in all probability, not have read my articles.

Prof. Lodge lays stress upon the fact that when two iron bars are welded by electric alternations, the circuit is completed in the first instance through a small section of iron only, such section becoming gradually increased, as the heat electrically developed renders the iron soft enough to be forced together mechanically, the whole section eventually being brought into electrical contact. I directed attention *more especially* to what was observed when a solid cylindric bar of iron was heated between the jaws of the electric welder, as will be seen from the following passage which appears in my published criticism of Sir William Thomson's paper on Lord Armstrong's accidental experiment:—

In the course of these experiments iron bars of as large a diameter as  $1\frac{1}{2}$  inches were welded, and *cylindric iron bars* of various diameters were heated to a white heat, a rectangular frame of cylindrical iron, forming a continuous circuit, was also placed in the jaws of the welding machine; this arrangement was something like a Wheatstone's balance, there being two paths for the current, which became divided through two arms of unequal resistance, the shorter conductor being only a few inches in length, and the longer one, say, four feet. The object of this experiment was to show that under such conditions the whole of the current practically passed by the shorter route, which became raised to a white-hot temperature, the longer one being grasped in the hand of a workman all the time the experiment was being performed.

Both Sir William Thomson and Prof. Lodge have assumed responsibility in respect to the development of the newer theory, and I invited them, on public grounds, to refute the *main* contentions of what I had brought forward, if they considered them to be erroneous. In my criticism on Sir William Thomson's paper, one of my contentions was, that what was seen to occur, when solid iron bars were heated in the electric welder, did not suggest in any way a crowding of the currents in the outer skin of the bar heated. According to the newer theory, when the iron frame forming a continuous circuit, referred to in the quotation, was placed in the welder, as the passage of the electric alternations through the mass involves overcoming inertia, the currents should have been crowded into the outer skin only, the central portion remaining "stolidly inert;" and further, seeing that the energy transmitted by the transformer was great enough to heat the section throughout to a white heat, if Sir William Thomson's explanation of Lord Armstrong's accidental experiment be the true one, then the outer skins of the two electrical paths through which the currents were being divided should have been too highly heated for the human hand to grasp.

In the article which has drawn forth this communication, Prof. Lodge has confined his comments to the electrically heating two iron bars forced together mechanically, and I cannot help thinking he has done so, because what then occurs is somewhat more complex, and therefore lends itself more readily to argument.

In the course of my articles, from common sense developments of older theory and direct observation, I have built up what I consider to be a very complete structure, every part of which harmonises with those well ascertained laws that are recognised by physicists generally.

The test we have a right to demand is that all developments of theory should harmonise with established laws, and render clearer what was known previously in part.

What led me in the first instance to oppose a theory, our mathematicians claim to be so great an advance forward, was the fact that it neither harmonised with, nor did it help us to more clearly understand, previous observations. I, myself, have reason to be thankful for having realised in my youth that two great principles—viz., harmony and continuity run through all physical phenomena, and any claims I may be considered fairly to have, either as a discoverer or pioneer of scientific advances, are attributable solely to a clear recognition that physical phenomena are all of them connected with one another, and that therefore one should suspect the truth of anything put forward, however plausible at first sight it may seem to be, if it does not harmonise with our *commonest* everyday observations. Those who really love knowledge for its own sake, and who find a pleasure in mastering the principles underlying all physical science, have often an intuitive feeling of the direction in which truth lies, and the discoveries they make are seldom accidental, they not uncommonly see truths a long way ahead, which they can look forward to realising, it may be years later, if only they are not in the meantime anticipated by some one else; but in these days of so-called advanced ideas the great thing sought for in public scientific lectures and presidential addresses is the sensational, something out of harmony with our humdrum everyday experience, and the more sensational it is, and the more it lends itself to argument, the more it is liked by the scientific talker who reaps a harvest of reflected glory by retailing and trumpeting the sensational utterances of greater men to audiences only too ready to be astonished and amused.

Those whom Society permits to make sensational presidential addresses are almost invariably men of distinction, having a deservedly recognised official scientific status, and, if criticised, the orthodox proceeding is to fall back upon professorial caste, and professional etiquette; should this fail, the arts of sophistry are commonly had recourse to, and exhausted.

In what I have published from time to time, since the Dr. Mann lectures of Prof. Lodge were delivered, I have traced the connection between a whole series of physical phenomena which mathematical physicists have regarded separately, and dealt with, as though they were not in any way connected. In this way I have been able to get round physical phenomena to some extent, and to look at them from several points of view, and, as a consequence, I feel that the position I have taken up, in respect to the newer electrical theory, is a very strong one. I go further than this, for I venture to express the opinion that both Sir William Thomson and also Prof. Lodge are well aware it is so.

The accumulated observations of a life largely devoted to scientific research has resulted in the development of a very simple theory, which, among other things, has enabled me to explain, in a natural common sense way, what at first sight seemed anomalous in Prof. Lodge's "Alternative Path Experiments." According to my theory, performing a physical act involves the overcoming of inertia—the overcoming of inertia involves a transformation of energy, and every transformation of energy involves a storage of energy in matter to the extent that inertia has been overcome. It will be found that by this simple theory all physical phenomena can be connected together in a continuous chain, and that they can all of them be traced back to a simple duality—viz., active or positive energy, and inertia or negative energy. The active energy is external to the matter acted on, and when it becomes associated with matter such association is a more or less unstable one. Negative energy, on the other hand, is inseparable from matter under all known conditions, and is the most characteristic feature of matter—viz., inertia or weight.

In all physical acts or transformations of energy, for they are convertible terms, the positive and negative energies concerned are necessarily balanced, similarly as is the case in electrical phenomena, and whenever a transformation of energy occurs, the transformation in some cases results in a temporary association of positive energy with the negative energy of matter only, and in others there results a more or less stable combination. As a case in point, interpose a copper conductor in an active dynamo circuit, a certain amount of energy then becomes transformed into magnetism at the time the circuit is closed, and energy will also be transformed into heat, the energy transformed into magnetism remains statically occluded all the time the circuit is complete, but the energy transformed into heat is only temporarily and unstably associated with the matter of the conductor in which it is developed; in fact, in some cases, as fast as energy is being transformed into heat it passes out of the conductor by radiation, and in other examples, such as electric welding, the heat becomes transformed and stored faster than it can escape by radiation, and in such cases there is an unstable association of positive energy with the matter of the conductor.

The transformation of energy into heat in an electric circuit is dynamic, whereas the transformation of energy into magnetism is a statical occlusion, and in all cases where positive energy becomes combined with matter, forming a more or less stable combination with it, the positive energy is statically occluded.

When a copper electric circuit is divided, the energy which was transformed into magnetism and statically occluded at the time the circuit was closed, is parted with *completely*, the copper conductor passing from the magnetically polar to the normal condition very rapidly, and the energy which remained occluded all the time the circuit was complete, becomes now dissipated through the medium of current developed during the act of demagnetisation. If an iron conductor be interposed in a dynamo circuit, the transformation of energy into magnetism that then occurs will be enormously greater than when a copper conductor is interposed; but when the circuit is divided, the energy transformed and occluded as magnetism will be parted with much more slowly than was the case with the

copper conductor, and some of it will be retained; the iron conductor, unlike the copper one, remaining more or less permanently magnetised; and here we have an example of a more or less permanent combination of positive energy with matter.

A plating bath is an example where no storage of energy occurs, or, to speak more correctly, where no work is done beyond that involved in overcoming conductive resistance, energy is certainly unlocked at the anode to the extent that the anode is broken down; but it becomes transferred to the cathode, where it builds up a structure the equivalent of that destroyed at the anode. In the case of a storage battery, where lead is oxidised, or a low oxide is converted into a higher oxide, altogether new structures are reared, and a very large transformation of energy occurs, the energy transformed becoming statically occluded in the new structure produced, which, being a very unstable edifice, readily parts with the positive energy entering into its structure whenever the conditions are at all favourable for doing so. Structures such as those developed in storage batteries are fairly comparable to fulminating compounds, which are simply very unstable structures, having relatively to their mass a very large amount of positive energy unstably occluded. From fulminating compounds we may pass to organic matter, such as wood or coal, and from organic matter we pass on by easy stages to such metals as gold or platinum, which are very stable structures, and not readily broken down.

The cases cited are a few illustrations of the way physical structures, and the forces associated with them, are all of them connected, and the simple theory developed by me, and published in the columns of this Journal, will be found to join them all in a natural, common-sense manner.

The most unstable association of positive energy with matter is undoubtedly a statical accumulation in a Leyden jar, and the next in order to this is a statical occlusion of energy in the form of magnetism in a copper conductor closing an electric circuit, for in both these examples there is no affinity between the positive energy and the matter it is associated with, the accumulation of energy being maintained solely by pressure.\*

Now let a mechanical illustration be briefly considered. (1.) Suspend a block of wood by a long string, and set it swinging by the hand; the whole of the energy imparted to the block in this way will practically take the form of motion, and it will be eventually, but slowly, parted with in the form of heat. (2.) Strike the block with a mallet and a percentage of energy will be at once converted into heat; but the greater percentage of energy transferred to the block will still probably be in the form of motion. (3.) Fire into the block a rifle bullet whose weight, multiplied by the square of its velocity, equals that of the mallet, and assume the bullet becomes buried in the wood, very little motion will be imparted to the block, nearly the whole of the energy associated with the bullet becoming transformed into heat.

Now let us consider what occurs when a Leyden jar discharges through an air space and a metal path. Energy accumulated as statical charge may be fairly regarded as a projectile unhampered by weight, whose speed under mentally conceivable conditions is infinitely greater than that of any rifle bullet, the time occupied by a Leyden jar in discharging being determined *solely* by the conditions that prevail in the path of discharge. Energy in the form of a statical electrical charge requires a path much in the same way as a fluid does, and space devoid of matter opposes as impenetrable a barrier to its passage as a solid mass of metal does to the flow of water; the path of discharge consists of an air space and a metal conductor, and as there is a great deal more matter in the metallic conductor than there is in the air space, and as inertia increases as the mass, it is in the metallic portion of the

\* The rate at which a copper circuit demagnetises, is determined by the conductive resistance of the circuit.

path that inertia is chiefly encountered, and where the transformation of energy mainly occurs.

The vehicle of transmission of a Leyden jar discharge is the electricity of the path itself, and if due allowance be made for the fact that neither energy nor its vehicle possess weight, then it will be found that a Leyden jar discharge comports itself in respect to metallic conductors very similarly to that described in reference to the mechanical illustration. In the mechanical illustration a much larger percentage of the energy was transformed into heat when the bullet was fired into the wood, than was the case when it was struck with a mallet; and so, also, a much larger percentage of the energy of a Leyden jar discharge, if of very high potential, becomes transformed into magnetism developed in the metallic conductor than would occur if the same amount of energy were statically accumulated in condensers having a much larger surface than the Leyden jar, and in which case the potential of the energy, and the rate of discharge through the paths, would be greatly reduced.

I have in previous articles emphasised the fact that the energy of a static charge is a limited quantity; and if I am right in maintaining that overcoming inertia in a metallic conductor is simply a transforming of energy into magnetism, then it follows as a truism that the greater the mass in the conductor the larger the percentage of the energy that becomes so transformed; and, further, that the magnetism developed, however large the conductor, can only approach to, but never exceed, the total amount of energy accumulated in the Leyden jar.

If only the continuity which runs through all physical phenomena be recognised, I think it must be seen how naturally what is observed in connection with Leyden jar discharges through metal paths falls into its proper place.

With the assistance of the newer development of electrical theory, Prof. Lodge has not been able to give a clear and intelligible explanation of his own "alternative path" experiments. My theory, on the other hand, not only explains Prof. Lodge's recorded observations in an understandable manner, but they become so plain and simple, that I have felt myself warranted in predicting that certain results will be obtained, if the alternative path experiments be repeated under certain conditions which I have specified. Now, if I can not only explain, but can also predict, where mathematicians cannot even explain, then it follows that my simple theory is a much more serviceable one than a complex theory, demanding the highest mathematics for its development.

My theory has been developed from direct observation and common sense reasoning, and I have shown in the course of my articles, that it has a much wider application than simply dealing with the experiments exhibited in connection with Prof. Lodge's lightning conductor papers. I have analysed inertia, which, as far as I know, no other physicist has ever even attempted to do. I have also, in no small degree, analysed the composite phenomena grouped together by mathematical physicists under the common term self-induction, and I have dealt also with the phenomena covered up by the term hysteresis.

In the analysis I have given of self-inductive phenomena, I have limited the term self-induction to the mutual induction between magnetised molecules on one another, and in my criticism of Thomson's paper on Lord Armstrong's accidental experiment. I called attention to certain matters in connection with electric welding, which I said I considered mathematicians could fairly claim as qualifying what was observed, and I pointed out that as iron loses its susceptibility to magnetism at a red heat when iron is raised to such temperature, the magnetic induction between molecule and molecule should cease, and therefore the inertia resistance opposed to rapid alternations in the direction of the electric currents should become very much reduced when a bar of iron in the welder reaches a red heat. Now I believe I am the only one who has pointed this out, and I was able to do so because of the

analysis I had made of the self-inductive phenomena which occurs in closed electric circuits, and which, as far as I know, no mathematical physicist has ever attempted to make. I am sorry to have to say it, but Prof. Lodge seems to me to have taken advantage of what I am the only one, I believe, who has called attention to, without giving me the credit for it, but the giving me credit for the accomplishment of scientific work is what certain of our physicists find it so difficult to do. I have not been trained in the orthodox schools, and I seem to be considered out of the pale of sectarian scientific salvation. The gist of Prof. Lodge's comments, which appears in *Industry*, relates to the reduction of self-induction which I suggested (in my criticism of Sir William Thomson's paper) would be found to occur after the iron bars had reached a red heat, but which *has not yet* been verified by experiment.

I venture to express the opinion that the newer development of theory is fundamentally unsound. Maxwell, its originator, has been credited with having successfully reduced all electric and electro-magnetic phenomena to stresses of the ethereal jelly; in other words, to stresses of a hypothetical entity, of whose existence there is no *real* proof, and therefore the ultimate basis of the newer theory is hypothesis pure and simple.\*

I cannot help thinking that some of our mathematicians would do well to take to heart the story handed down in reference to Archimedes. Archimedes undertook to move the earth, if only a base outside it were given him; the base he required was not forthcoming; that being so, we may be very sure he never wasted his time attempting to move the earth. Mathematicians, be they ever so able, can no more build up sound theory without an absolutely sound basis, than Archimedes, in the absence of a base, could move the earth. At the risk of being considered dogmatic, I venture to go further than this, and to express the opinion that the basis of all man's theories must be a material one, that is to say, the basis of theory must consist of direct observations associated with matter. We know just a little about matter and the forces associated with it, and no more, and what we do know has been learned from observation. Sir Isaac Newton never attempted to define gravity, he simply observed gravity's laws, the dogmatic utterances of Nature, and these utterances, *not* hypothesis, gave him a basis *absolutely* sound, which his mathematical ability was able to turn to splendid account. The great work associated with Joule rests ultimately on direct observation, and the same can be said of the mechanical theory of heat, whose basis was the observation, that when atmospheric air or other-gas performed work in the act of expanding heat disappeared. No man can explain why this is so; it is simply a dogmatic utterance, and the ultimate basis of all true science consists of the dogmatic utterances of

\* If any physicist could have evolved a true hypothesis, it will be generally admitted that Maxwell could have done so, but it passes the wit of any man to do this; the writer has a lively remembrance of the only time he had the pleasure of meeting Maxwell and discussing magnetism with him; had the writer not been aware he was speaking with the great physicist, Maxwell's large dreamy eyes and general physiognomy would have suggested the poet rather than the mathematician. With regard to the existence of the hypothetical medium, ether, the writer admits the necessity of some such assumption. As far as observation goes, no communication between matter and matter can occur, excepting through a medium, and such medium, as far as can be seen, must be of the nature of a material one. Energy, when associated with electricity, requires a path, and evidence is forthcoming which seems to necessitate a medium of some kind for magnetism to be transmitted; that being so, it seems a fair inference that a vehicle is necessary for the transmission of energy; in any case, our imperfect knowledge renders such an assumption almost a necessity; but if an attempt be made to define the nature of the medium which has to be mentally conceived, it will be found that the medium must be assumed to possess both positive and negative qualities at one and the same time, and such a conception makes as large a demand on our credulity as the Athenian Creed itself. As we cannot altogether dispense with mental assumptions, it is legitimate enough to avail ourselves of them; but the writer's contention is that it should never be lost sight that they are mere assumptions, which cannot possibly form a base on which a scientific structure can be safely reared.

Nature, which we become acquainted with only by observing. The human intellect is very limited. It is equal to observing and building up observations, but it *cannot* create; and it does not seem capable of travelling, with safety, outside the limits of matter; and further, all science, if only completely grasped, can be explained by *common sense reasoning*, which, unfortunately, school training has a tendency to cripple.

If anyone will perform the task of carefully going through "Modern Views of Electricity," which is not the easiest of reading, he will find the newer development of theory to consist of a series of hypotheses, resting upon one another, and resting ultimately on hypothesis also, and every one of these hypotheses is taken for granted as being absolutely true.

Sir William Thomson, addressing a body of engineers as their President, not only told them that electric alternations were confined to the outer skin of a conductor, but he told them the actual depth they would enter under conditions he specified; in this address Sir William overlooked altogether the transformation of energy into magnetism, and its subsequent transformation into current during the demagnetisation which occurs between each alternation. I have pointed out in my articles that the current produced by the demagnetisation of a conductor is developed throughout the whole section, and is at a somewhat higher potential in the centre, and if I be right in my contention that transient currents pass through the mass of the conductor, then the energy transformed into magnetism and subsequently into current, whenever rapid alternations are transmitted, must represent a very considerable percentage of the energy.

Sir William Thomson cannot deny that the currents produced during the act of demagnetisation of an electric circuit are developed throughout the mass of the conductor; but according to the newer theory, there would be but little transformation of energy into magnetism, and, possibly, Thomson regards the current so produced as a negligible quantity, and considers that what transformation occurs between each alternation is covered by the term hysteresis. I am very sorry the word hysteresis has come into common use; I believe the term is due to Prof. Ewing, for whom I have the greatest respect, and to whom I have the best of reasons for feeling indebted. My reasons for objecting to the coining of terms is that they are too often employed to cover up problems, and to decently bury what ought to be faced. I do not want to claim more than I have a right to; but I think I have given a generally correct explanation of what occurs in a conductor when rapid alternations are being transmitted, and which the term hysteresis, as I understand it, covers, but does not attempt to explain; in any case, I have discussed the matter, and that is something.

A Leyden jar discharge through a metallic conductor is undoubtedly the most transient electric current we are familiar with, and therefore inertia phenomena should be accentuated in the highest degree when a Leyden jar discharge takes place through a metallic path. Now, I should like to ask Sir William Thomson: (1) What evidence he can produce that the transient current of a Leyden jar discharge through a conductor of large section is confined to the outer skin? (2) What evidence is there forthcoming which goes to show that electric alternations transmitted by a transformer through solid cylindric iron bars are crowded into the outer skin.

I do not think (1) that it can be a matter of contention that in the alternative path experiments the B spark arises out of the demagnetisation of the path, L; (2) that the recorded observations of Prof. Lodge demonstrate that the discharge of a Leyden jar is completed in a less time through a No. 1 B.W.G. copper wire than through a No. 19 copper wire, the section of which is 100 times less than that of a No. 1 B.W.G. wire; (3) that the B spark is greater with the No. 1 wire than with a No. 19 wire; (4) that the spark at B, being due to current developed by demagnetisation, the greater spark observed in the case of the thicker wire indicates a greater transformation of energy

into magnetism at the time of discharge, and this must be taken as demonstrating that the discharge passed through a larger mass of matter, for it seems clearly evident that if the discharge were confined to the outer skin of the conductor only, it would pass through a thinner skin in the case of the larger conductor on account of its greater surface, and the spark at B would have been less, instead of being greater, as it was found to be by Prof. Lodge.

The alternative path experiments of Prof. Lodge—explained as they are, without any straining, by my simple theory—seem to me to prove my contention up to the very hilt.

Prof. Lodge cannot possibly object to his own experiments, and I assume Sir William Thomson accepts the recorded observations of Prof. Lodge in connection with these experiments. Now I should like to ask Prof. Lodge, and also Sir William Thomson, whether I have not made a fair analysis of the "alternative path" experiments; and I would further ask these two distinguished physicists, who have assumed responsibility in respect to the newer development of theory, on public grounds, not to maintain silence. I do not like to think that either Sir William Thomson or Prof. Lodge can have any other desire than the development of scientific truth; and I ask them, therefore, to meet me frankly and straightforwardly. My main contentions are plain enough, and admit of plain answers; and I do hope, if I am honoured by criticism, such criticism will not be confined to the outer skin of my arguments.

#### STENO-TELEGRAPHY.

UNDER the name of steno-telegraphy, Mr. G. A. Cassagnes designates a new telegraphic system, founded on the combination of mechanical stenography with telegraphy.

The apparatus is an adaptation of the stenographic machine of Michela in which, by means of 20 signs and their combinations, all possible phonetic sounds can be represented. As soon as spoken, the words are, so to say, decomposed by the ear of the operator at the key-board; the graphic representation of syllables is printed in small distinct lines on a tape of paper, and there only remains afterwards to read these lines from left to right to reproduce the language spoken, whatever it be. It is stated that an operator can, after about six months' practice, stenograph from 150 to 200 words per minute in a language with which he is familiar, which is more than is necessary to follow the fastest speaker. Fifteen days are said to be sufficient to learn to read the tape fluently.

M. Cassagnes's invention has for its object to reproduce at a distant station the stenographic tape that Michela's machine produces, *in loco*, and at the same speed. The object is effected with a single wire and an arrangement of the multiplex system in which the La Cour phonic wheel plays such an important part, the La Cour method of synchronism being adopted.

The distributor with its trailing arm has 20 sectors, or groups of sectors, each corresponding to one of the 20 signs referred to.

A large number of practical experiments have been made with the apparatus on looped wires (properly arranged with earth connections), and also on direct wires with the instruments at the ends of the wires between Paris and Lille, the route followed being circuitous, and the greatest length 770 kilometres. In all cases the results are stated to have been most successful, the output of work being very much greater than that obtained on the ordinary telegraphic system.

We must remark, however, that with the apparatus arranged to work as an automatic system, *i.e.*, using perforated tapes, the maximum speed appears to have been 400 words a minute which is quite equalled in this country by the Wheatstone automatic system, with its less complicated mechanism.

**ELECTRICAL ENGINEERS AT EDINBURGH.**

ABOUT 70 members of the Institution met in the phonograph room of the Exhibition on Tuesday last to hear papers read. Dr. Hopkinson, in his capacity as Chairman, expressed satisfaction at seeing a good number of members present to enjoy the kind hospitality of the Executive Committee of the Exhibition.

At the commencement of the business the secretary announced that Sir Archibald Campbell would be pleased to see any members of the Institution at his works on the Clyde. Several gentlemen of Edinburgh were also anxious to receive members of the Institution as guests, an anxiety which would doubtless be relieved.

Dr. Walmsley read a paper on some of the chief features of the Exhibition, a subject exhaustively treated in the pages of the REVIEW. Mr. Bennett followed with a paper on "Foreign Currents in Telegraph and Telephone Lines."

In the evening the Executive Council gave their reception in the Concert Hall to the members. Several articles and scientific instruments were specially exhibited.

The meetings were resumed on Wednesday morning, Mr. W. H. Preece in the chair. The paper on "The Working Efficiency of Secondary Cells," was, in the absence of Prof. Ayrton, read by Mr. Lamb, one of the joint authors. A discussion followed, which we shall publish at the end of the paper, which we partly produce in this issue of the REVIEW.

After the reading of the papers, a party of the engineers and friends left in the afternoon for Queensferry, to view the Forth Bridge. The male portion alighted from the train at north end and walked over the bridge. Reaching the other side a launch was chartered which conveyed the whole party under and about the bridge. It is needless to say, the structure was generally admired.

**THE TELEGRAPH CLERKS AND THE  
NEW SCHEME.**

WITH a praiseworthy alacrity which has probably astonished even their best friends, and which is generally considered foreign to the deliberations of that administrative body, the Lords of the Treasury have considered, sanctioned, and returned to the Postmaster-General the recommendations submitted to them by him, and which have for their object the general improvement of the position and prospects of telegraph clerks in the service of the Crown.

The provincial readjustment has, it is stated, given satisfaction in various quarters; but it would be premature to judge of the general feeling at so early a period, more especially as its application has yet to be effected. We may, therefore, take the reported provincial approval as being at present largely prospective. Dealing with the proposals which immediately concern the numerous and ever-increasing staff at the Central Telegraph Department, London, we find that the Postmaster-General's offspring has been presented to them without a head. This has probably got knocked off, or, as the official phrase has it, been "delayed in transmission"—whether designedly or not, we cannot say. But the fact remains, and, to put it in a simple way, it is a column lacking its most interesting and characteristic feature—namely, its capital.

We cannot but admire, as we are sure all telegraph clerks will appreciate, the thoughtful, considerate, and, we feel inclined to add, generous spirit with which the base and trunk of the Postmaster-General's work have been invested.

In this direction we observe that where leave cannot be granted on Bank Holidays, extra pay will be awarded. The official intimation of this, as of several other points in the scheme, is vague and

ambiguous to a degree. This may be due to hasty drafting, together with a desire to give immediate information to the staff; at all events, it is to be hoped that it has not been intended as a suitable adjunct to the missing "capital," to which we will refer more fully hereafter.

The ambiguity of this document is probably also the cause of the more important announcements contained therein being received with, as we hear they have been, dissatisfaction and distrust.

Another generous concession, and one for which telegraph clerks will not fail to heartily thank the Postmaster-General, is that all overtime shall be paid for at what is known as "rate and a quarter." Knowing as we do that through a heavy—nay, almost a necessitous and often unforeseen—demand on the one hand, and, generally speaking, a ready response on the other, much extra time has to be performed, we cheerfully recognise both "just and generous" consideration here. This, and the Bank Holiday arrangement, will be common to the whole service.

Provincial clerks will be paid overtime for Sunday work, an emolument always given to London men. In a somewhat uncertain manner it is stated that annual leave will remain as before, and we accept this as meaning that clerks receiving £150 per annum and upwards will receive one calendar month's leave.

There is a reasonable possibility that clerks, in a scale which extends to £160, are entitled to the same period.

The leading features of the scheme, however, are the monetary reforms.

Clerks in the second class will, after a period of probation, say, about two years, go from £45 or £46, by £6 per annum, to £110—old maximum £100, by £5—£110 after 14 years' service; certainly not a dazzling prospect! 1st class, £110 to £160, by £6, an increase of £20 on old maximum. We find that a first-class clerk will have served 22 years and upwards for this sum, unless in the earlier stage some encouragement, in the shape of double increments, is forthcoming. We do not think him likely to appreciate his position, and for reasons which will require little explaining.

We have already said that the Postmaster-General's column lacks its capital. The official announcement refrains from holding out any prospect whatever as to a first-class clerk's promotion to the senior class. The case of the senior class, as at present constituted, is under consideration, and the most adverse rumours are in circulation. Many first-class clerks, who have been told that they are "worthy of every encouragement," have already been waiting two, and in some cases, nearly three years at the top of their class at £140. They have seen colleagues with no more, and a few with considerably less service promoted to the next or senior class. These latter will attain Mr. Fawcett's maximum of £190. The former, who had been contemporary with them, through being what is officially termed "unlucky," will, after 25 years' service and upwards, find themselves in receipt of £160, and with absolutely no prospect beyond that figure held out to them. The Postmaster-General's decision with reference to the scheme is the "capital" to the "column." His decision being withheld, though even briefly, robs his labours of what should be their crowning glory. We can see here why the staff have a dislike to receiving schemes by instalments. It is to be hoped, in the interests of the public service and also of its servants in the Telegraph Department, that a fair and free prospect of at least attaining Mr. Fawcett's maximum of £190 or, better still, £200, will be given to all meritorious and deserving men.

As we have already said, much in the Postmaster-General's scheme commands our unqualified praise, and we recognise therein consideration and even sympathy for the more ordinary privileges and comforts of the telegraph clerks as a working body both in the concrete and the abstract.

The delay in dealing with what we have termed the "capital" question will be happily incurred, provided it results in what we trust will be a just and liberal

recognition of the claims of the hundreds upon hundreds of telegraph clerks who are anxiously and earnestly awaiting the creation of what is commonly known as a "reasonable prospect." Such a step would, we feel assured, set the seal to the Postmaster-General's work, his reward would be found in the spread of a gradual, yet, nevertheless, general and abiding contentment throughout the service, agitation would have only one object—to languish and die—the lack of cheers and excess of jeers of which we have heard far too much on recent occasions—as we have also of the "violent assault" case, to which we merely refer, and which has, we imagine, been distorted and exaggerated beyond all reason—would give place to a hearty and earnest union of interests, tending to the advantage and satisfaction of the public, and the commercial success and progress of the telegraph service, throughout the country.

## NOTES.

**Newry and the Light.**—The Town Commissioners have refused their consent to the application of the Irish House-to-House Electric Light Company to light the city.

**Sheffield Lighting.**—A special meeting of the Town Council has been called to consider applications by electric lighting companies. The *Sheffield Independent* suggests that the council should itself apply for powers.

**Weymouth Lighting.**—Messrs. Latimer Clark, Muirhead & Co., London, intend to apply to the Board of Trade in the next session of Parliament for a provisional order to supply electricity in the town.

**Proposed Electric Lighting at Worthing.**—The Laing, Wharton and Down Construction Syndicate, Limited, notify their intention of applying for a provisional order enabling them to supply the electric light within the jurisdiction of the Corporation of Worthing. The local authority has referred the subject to a committee, who will recommend whether the application shall be assented to or opposed.

**Competitive Electric Lighting at Southampton.**—Several companies are in the field anxious to obtain the necessary orders to enable them to supply the electric light within the Borough of Southampton, among them the South of England House-to-House Electricity Company, the Electric Installation and Maintenance Company, the Southampton Electric Light and Power Company, and the National Electric Supply Company. The Town Clerk has written to these rival companies informing them that it was not at all probable that the Corporation would assent to their applications; and the House-to-House Company has replied that in the event of the Corporation deciding to undertake the supply of the electric light, it would not proceed with its provisional order, but offer the Corporation every assistance.

**Electric Lighting at Brighton.**—At a special meeting of the Brighton Town Council on Thursday, contracts for the erection of buildings for an electric light generating station and for other works, were ordered to be entered into forthwith. Alderman Ewart said that the electric lighting scheme was the beginning of an enterprise which would make Brighton more popular than ever. The sooner every hotel, lodging house, and the important thoroughfares were lighted by electricity, the better it would be for the town.

Pertinent questions are being asked with reference to the tenders for supplying the electrical plant in Brighton. In one instance, that of dynamos, the highest tender was £11,946, and the lowest £6,975. Why this difference queried Col. Tester? It is also suggested that the successful contractors were unduly favoured by the Lighting Committee's engineer.

**Exeter and the Electric Light.**—There was a discussion at the last meeting of the Exeter Town Council, anent the desirability of the corporation undertaking to supply the "light of the future" to the inhabitants, instead of allowing private companies to establish a monopoly in the city. The Devonshire Electric Light and Power Supply Company, Limited, has given notice of its intention to apply for a provisional order, and in view of this, it was decided to appoint a committee to consider the desirability of the corporation taking steps to obtain the necessary electric lighting powers.

**Berlin Lighting.**—Notwithstanding the satisfactory arc lighting in the Kaiser Wilhelmstrasse and the Unter den Linden, it is not, says the *Electrotechnische Echo*, intended to extend the public electric lighting for the reason that the perfection of gas lighting produced by competition is expected to give the same result with less cost.

**The Lighting of Dusseldorf.**—A central electric station proposed for the town was to have had a capacity of 10,500 lamps of 16 candle-power, but owing to the demand it is decided to enlarge the scheme to a capacity of 18,000 lamps, and new tenders are invited. Most of the tenders sent in were for continuous current with accumulators.

**Woolwich Lighting.**—The Woolwich Electric Company and the London Electric Supply Corporation have both notified to the Woolwich Local Board of Health their intention of applying to the Board of Trade for provisional orders to light Woolwich by electricity. A special day is to be devoted to consider the applications. There appears a disposition amongst the members of the board to favour the local company.

**Canterbury Lighting.**—By a majority of one the Canterbury Corporation has resolved that pending the granting and confirmation of the provisional order to be applied for by the council, application be made to the Board of Trade, authorising the council to supply electricity for public and private purposes within the city. If the licence be granted, it is proposed to commence operations at once.

**Electric Light at Bridlington.**—The Laing, Wharton and Down Construction Syndicate has fitted up the Prince's Parade at Bridlington with 1,200 candle-power arc lights. The lamps were working for the first time on Saturday last before a gay and fashionable assemblage.

**Croydon Lighting.**—The Corporation of Croydon has decided to apply for parliamentary powers, with the intention of selling its rights or not, as it pleases, to a company.

**Leamington Lighting.**—The worthy folks of Leamington still appear to have a very bad impression of the electric light, Mr. Crowther Davies, at a council meeting, characterising it as "eminently unsatisfactory."

**Winchester Lighting.**—Tenders are invited for lighting the city and municipal buildings by electricity.

**Breaking Telephone Insulators.**—Six Birmingham boys have been fined 5s. each for damaging wires and insulators belonging to the National Telephone Company at Smethwick. About 150 insulators were broken, and serious interruption caused to the service. Over 12,000 insulators had already been broken in this way.

**Sensational Reporting.**—In describing an accident at the Californian Electric Light Company's Works, a San Francisco reporter states that "the volts (big fellows, weighing 20 lbs. each) whizzed through the air with the velocity of cannon balls, and buried themselves in the walls of the establishment. One man was injured, though not seriously." A New York exchange suggests that he may have been hit by one of the flying volts.

**Laying of the Tory Island Telegraph Cable.**—On the evening of Wednesday, the 9th inst., at 7.30 p.m., the opposite ends of the telegraph cable between Tory Island and Pollaguill, on the mainland, were brought together and united. From that moment the long-talked-of project of telegraph communication between Tory Island and the mainland had become a reality, and the "Sentinel of the Atlantic" is now connected by telegraph with every shipping office in the British Isles. The contractors with Lloyd's for this work are the India-Rubber, Gutta-Percha and Telegraph Works Company, of Silvertown, London. The steamer *Buccaneer* was in charge of Captain D. Wilson Barker, R.N.R., the expedition being under the direction of W. H. Gray, Esq., engineer-in-charge, with Mr. Edward Stallibrass, assistant engineer, and Mr. J. Schneider, electrician. The cable is one of special construction. The shore end extends about a mile at each end, and weighs 17 tons to the mile. It has two cores and two sheathings of galvanised wire, with an outside protection of hemp cords and bituminous compound. The cores are protected against insects by brass tape. The main or deep-water cable weighs about  $7\frac{1}{2}$  tons per mile, and has but a single sheathing of wire. The underground or Tory Island end of the cable weighs about two tons to the mile, has one sheathing of galvanised wire, and has a protection of tarred cotton tape. In order to inform passing ships of the telegraph line, and as a protection against vessels casting anchor over it, one large buoy is placed over the cable about a mile south of Tory, having on it the word "Telegraph" in conspicuous letters. Nothing remains but to complete the arrangements for laying the land-line on Tory. Full directions have been given by Mr. Gray to have this work accomplished, and an officer from the Post Office is also making preparations for the erection of poles and connecting the wire between Pollaguill and the telegraph office at Dunfanaghy. By the kind permission of Mr. Gray and Captain Barker, a number of ladies and gentlemen at Dunfanaghy eagerly availed themselves of the rare opportunity of witnessing these scientific experiments in electricity, and the practical routine pursued in laying deep-sea telegraph cables, and at the same time of seeing Tory Island, and while on board the *Buccaneer* the visitors were most hospitably entertained by the officers engaged in the expedition.

**Tenders Wanted.**—Tenders for the electric lighting of Stockholm are invited, the same to be sent to the Director of Gasworks, Stockholm, by September 1st. Particulars may be seen in our advertisement pages.

**Electric Traction.**—*Money*, in announcing the formation of two more electric traction companies, says that until the traction companies agree to work by electricity a good stretch of line, nothing but experimental and commercially unsuccessful short lines will result.

**A Gaulard Monument.**—A statue to the late M. Gaulard will be inaugurated in the course of the month at Lanza, Turin. Gaulard will be represented crowned with laurel and oak leaves, and at his feet will be sculptures in low relief, emblematical of his achievements in the domain of electricity and of his untimely death. The monument is by Cesare Biscarra, of Turin.

**The Electric Welding Company.**—The *Stock Exchange* understands that this company, when brought out, is likely to be attacked by the electrical papers on the ground of over-capitalisation. Our contemporary is not far out in its calculations.

**Electric Traction in the States.**—The Spring Garden Avenue Street Car Line, of Pittsburgh, is going to be turned into an electric road.

**Personal.**—We have received an intimation that Mr. John Pearce has commenced business as an electrical engineer at 182, West Regent Street, Glasgow.

**Secondary Batteries.**—The paper on "the Working Efficiency of Secondary Cells," by Messrs. Ayrton, Lamb, Smith and Woods, read at the Edinburgh meeting of the Institution of Electrical Engineers, contains much valuable information. There is little in the paper, however, which has not been said before, but it must be conceded that the authors have treated several important points in a most exhaustive manner, and they have furnished experimental proofs on certain phenomena concerning which much doubt has hitherto existed. We must congratulate Prof. Ayrton and his assistants upon the thorough manner in which the task has been performed.

**The Central London Railway Bill.**—The Committee of the House of Lords has decided that the preamble of this Bill "is not proved."

**Wimbledon Lighting.**—It appears that the Wimbledon ratepayers do not take kindly to a circular and accompanying form which Mr. Arthur Holland, chairman of the electric lighting committee, is sending to probable users. A letter in the *Wallington Herald*, of the 12th inst., from Mr. A. Ward, throws much light upon the matter.

**The Old and the New.**—The Old Hall, which now forms a portion of the works of Messrs. Clarke, Chapman & Co., of Newcastle, is the house described by Charlotte Brontë in her famous novel, "Jane Eyre." The place is now virtually the firm's lamp factory, and in the entrance there is fixed and in use what is said to be the largest incandescent lamp in existence.

**Fire Office Rules.**—Mr. John B. Verity writes as follows:—"I venture to trespass on your valuable space in reference to a matter which is engaging a considerable amount of attention amongst electrical contractors at the present time, viz., Fire Office Rules. Formerly most contractors carried out their work as nearly as possible in accordance with the Phoenix Rules, but now every fire office has a special set of rules for electric lighting on its own account. This was, of course, to be expected, as competition among insurance offices is as keen as in any other business. What is the electrical contractor to do? In an important installation the building and contents are often insured in three or four leading offices, all of whom ask if the work has been carried out in accordance with their particular rules; and how can this possibly be done when the rules vary in important respects? It seems to me that the sole remedy is for the electrical contractor to work carefully in accordance with the rules laid down by the Institution of Electrical Engineers. If these rules are considered insufficient in any particular respects, contractors will soon hear of it, and where there is any consensus of opinion, a report should be made to the Institution, and a periodical revision of the rules undertaken by a committee. This, I believe, would do away with the present hopeless condition of affairs, when a surveyor from one leading office expresses great satisfaction with work one day, and the next day a surveyor from another equally important office swoops down and harasses the contractor by demanding alterations which can best be described by F.A.D. in capitals."

**Edinburgh Tramways.**—The question as to the future management of these tramways is beginning to arouse public interest. We may yet possibly see electric traction advocated.

**Connoisseurs from Bristol.**—The Bristol Electric Light Committee has been prowling about in the small hours of the morning, under the guidance of Mr. Preece. Several stations, including Brompton, Sardinia Street, Manchester Square, and Deptford were visited, and Mr. Preece's house was eventually invaded, the committee leaving town with the impression that electric lighting is, at the best, 25 per cent dearer than gas.

**Lighting Newspaper Offices.**—The offices of the *Sportsman*, in all departments, have been fitted with the electric light, in a manner most satisfactory to the proprietors of that journal, by Messrs. Arthur B. Gill and Co.

**A New Insulator.**—The Kinetic Engineering Company sends us the following:—"With reference to the paragraph in your last issue upon what is termed a new type of Berthoud-Borel cable, kindly permit me to say that not only has no such type of cable ever been manufactured by the Berthoud-Borel factory, but that no one connected therewith would ever dream of using such substances as celluloid or tarred hemp for the purpose of cable insulation."

**The Bermuda Cable.**—A New York telegram of last Friday states that communication by submarine cable between the Bermudas and Nova Scotia has been satisfactorily established. The first cablegrams were interchanged between Halifax and the Bermuda station the previous day.

**The Halifax and Bermudas Cable Company.**—The following is a copy of a telegram received by the chairman from the Governor of Bermuda:—"The Chairman of the Halifax and Bermudas Cable Company, London—Many thanks for your message. I warmly congratulate the company on the successful laying of their cable, and sincerely wish them every prosperity."—NEWDEGATE, Governor, Bermuda.

**Telephonic Communication between London and Provinces.**—Last Friday afternoon a wire to London, which was completed late the previous night, was tested at the offices of the National Telephone Company, Faulkner Street, Manchester. Alderman Thompson, who was attending a meeting of the directors of the company at the Cannon Street Hotel, in London, and other gentlemen held conversations with representatives of the Press and others in Manchester, and not only were the words uttered heard quite clearly, but the tones of each voice were recognisable. The new wire, we understand, extends from Sheffield to London, and terminates at the office of the company, Oxford Court, Cannon Street. There is already existing a wire from Sheffield to Manchester, and the two wires were placed in circuit. The gentlemen at the offices of the company in Faulkner Street, Manchester, were thus enabled, with the most perfect ease, to speak to officers of the company in London. Colonel R. R. Jackson, one of the vice-presidents of the company, was one of the gentlemen in London who conversed with representatives of the Press in Manchester. London to Manchester is 221 miles; to Liverpool *via* Manchester, 266 miles; to Sheffield, 195 miles; to Bradford, 252 miles; to York, 275 miles; and to Leeds, 252 miles. It is expected that in the course of a fortnight the London wire will be available for the use of the members of the Exchange in Manchester. Telephonic communication between London and Liverpool was also established last week. Messages were first exchanged between the Mayor of Liverpool and London, and during the afternoon several commercial messages were transmitted. The opinion of those who tested the telephone was that, though 200 miles separate, London and Liverpool messages will be as distinctly heard as if they were transmitted between the local centres.

**Fatal Accident at Blackpool.**—A little boy was last week knocked down by an electric tramcar while crossing the promenade near the Foxhall Hotel, Blackpool, and received such injuries that death resulted almost immediately. The driver of the tramcar was not to blame. The roadway is very narrow at that point, and the little fellow was in front of the car before it could be stopped.

**Telegram Paper.**—A firm of London estate agents bitterly complains of the flimsy pink paper supplied recently for telegrams. For several cogent reasons a change for the better is suggested, in which we entirely concur.

**The Telephone in Italy.**—Telephonic communication is to be established between Rome and Naples, Florence, Genoa, Turin, Milan, Venice, Spezzia, as well as between Turin and Milan, Milan and Venice, Genoa and Turin, Genoa and Florence, Naples and Palermo, and Messina and Palermo.

**Earthquake Shocks and Telegraphic Cables.**—The Eastern Extension Company has had to notify the interruptions of telegraphic communication with Australia by the sudden and simultaneous breakage, on the morning of the 11th, of their three cables between Java and Australia, presumably by earthquake, as shortly before the interruption a shock, said to be the sharpest felt for many years in the neighbourhood, passed over Bangoewangie, at the eastern end of Java, close to which all three breakages occurred. Restoration of communication was expected in about a week's time.

**The Electric Light at Woking.**—The laying of mains for the supply of electric current for illuminating purposes is now proceeding, the mains having been laid underground as far as the railway arch on Goldsworth Road. Everything is expected to be in readiness by the 1st October, and experimental lighting is to take place before that date. A meeting of ratepayers of the parish is to be convened at an early date to take into consideration the desirability of publicly lighting Woking Station district.

**Mahla's Carbons.**—Messrs. Cathcart and Peto have been appointed sole agents in the United Kingdom for the sale of Mahla's electric light carbons. In addition to excellence of quality, unusual whiteness of light and great efficiency is specially claimed for these carbons.

**The Whitehall Club.**—A very good and representative meeting of the electrical members of the Whitehall Club met at dinner on Thursday evening, last week, Dr. Hopkinson presiding. The general feeling of the gentlemen present, who, with a few guests, numbered about 30, was distinctly against anything approaching cliquism, and we imagine that those who have joined the club will simply act their parts as ordinary members without any reference to representing an electrical section of the engineering profession. Messrs. Albright, Sellon and Killingworth Hedges may be congratulated on having secured the subscriptions of a larger number of gentlemen than was actually requisite to meet the concession of the committee, and to participate in the privileges of becoming members of the Whitehall Club.

**Kilmarnock Chemical and Electric Works.**—Messrs. J. and J. Blair intimate that they have added to their business a department of electrical and mechanical engineering, which will be under the immediate superintendence of Mr. James Campbell, late of Anderson, Campbell & Munro, Limited, Hyde Park Electric Works, Glasgow.

**The Compound Winding Case—Judgment Sustained.**—The first judgment in the compound winding suit between Messrs. King, Brown & Co., of Edinburgh, and the Anglo-American Brush Corporation, has been sustained in the appeal case. We shall give the complete text of the decision in our next; but append hereto the precise words of the Judge:—"I am of opinion that the interlocutor of the Lord Ordinary should be adhered to, and decree of reduction of patent pronounced." (The Lord President.) That is the opinion of the Court. On the motion of Mr. Daniell, counsel for Messrs. King, Brown and Company, the Brush Corporation was found liable in expenses.

**The Electric Light at Weybridge.**—At last week's meeting of the Chertsey Rural Sanitary Authority, notice was received from the Laing, Wharton and Down Electrical Construction Syndicate, Limited, that they intend to apply to the Board of Trade for a provisional order for the lighting of Weybridge under the Electric Lighting Acts. The clerk was directed to give special notice that the subject would be considered at the next meeting of the Authority, on August 19th.

**Incandescence Lamps.**—The Brush Electrical Engineering Company, Limited, has acquired the Edison lamp patents for Australasia, India, the Cape of Good Hope, and Natal, and notifies that it is an infringement of the rights now secured by assignment to that company to import, sell, manufacture, or use any incandescence electric lamps in those colonies except under licence from the company. While the Brush Electrical Engineering Company is resolved to assert and to maintain its rights, it will supply incandescence lamps at prices not higher than those which now generally prevail in the colonies.

**Fast Telegraphy.**—We print elsewhere a brief description of the steno-telegraph, a system devised by M. Cassagnes for dealing quickly with a large quantity of telegraph work. In a report by a M. Despeissis on the system, it is stated that steno-telegraphy gives one of the most practical solutions to the problem which has to be faced to-day more than ever, by all telegraphic administrations, viz., the clearing up of their wires. It would seem that the writer is ignorant, not perhaps of the Wheatstone automatic system, but of the capabilities of that system as worked in this country, for satisfactory as the steno system is stated to be, it is certainly quite equalled by the Wheatstone when properly manipulated.

**An Electrical Effect.**—A correspondent, writing to *Nature*, draws attention to a simple experiment which is an interesting variation on the ordinary mode of performing the experiment of putting pieces of zinc and silver in the mouth and touching them, to obtain the acid taste which accompanies the completion of the electric circuit. If the piece of zinc be placed under the tongue, and a florin vertically between the upper lip and the top row of teeth, and the two metals be brought in contact, a faint flash is seen in both eyes when the eyes are open. If the eyes are shut the sensation of light is not felt, so that the effect is probably due to a muscular twitching. It is necessary to use a large silver coin, and not a shilling, and to push it well home behind the upper lip. We are under the impression that this effect is mentioned by Tyndall in his "Electricity," and that the effect is stated to be due to the electric action on the optic nerve.

**The Villard Syndicate.**—A Milwaukee despatch says:—"The three principal street railways of Milwaukee are to be consolidated, under control of the Villard Electric Syndicate. Bonds covering all three properties, the Becker line, the Milwaukee, and the Cream City, are to be issued in place of those now outstanding. About \$2,000,000 new stock and bonds are to be issued. Villard people acquire 50 miles of double track by equipping electrically and taking securities in return." According to another:—"A deal involving upward of \$5,000,000 and including a transfer of a controlling interest in the Badger Electric Light Company, the Edison Light Company, and the Cream City and Milwaukee Street Car Companies, is said in the American papers to have practically been consummated. The purchaser is the so-called Villard syndicate, including Henry Villard and Ryan, the Pittsburg capitalist. But Milwaukee capitalists will still retain an interest in each of the corporations, although there is a complete change of owners in the Badger Electric Light plant. The purchasers outside of the Villard syndicate are the same Milwaukee men who are interested in the Edison Electric Light plant now being built."

**Private Central Electric Lighting Stations.**—It is perhaps a little surprising that so little has been done in the way of private central electric lighting stations; the cause of this has no doubt been due to the very indefinite information which is to be obtained with reference to the economy of the electric lighting system; this, of course, makes householders hesitate before they commit themselves to a plan which may prove unexpectedly expensive, and, they also probably think, troublesome. Far and wide as the electric light is spreading, its advantages are still very far from being understood, and it still requires to be forced into notice. In one or two cases private central stations have been successfully started, and notably at Kirkton Hill, Dumbarton, where Mr. Denny, whose own residence has been lighted for some years by a separate plant, has induced a number of householders to have their houses electrically lighted. Some precise facts as to expense with reference to this and similar plants would be highly useful.

**Deaths from Electric Currents.**—A correspondence between the Foreign Office and the Board of Trade, with reference to deaths from electric currents in the United States, has just been issued as a Parliamentary paper. It appears that the United States Census Office is not at present in possession of the *data* necessary to enable it to furnish the information desired, but the New York municipal authorities state that from January 1st, 1887, to May 15th, 1890, there were 16 deaths from electricity in that city. The Foreign Office and the Board of Trade might have consulted the ELECTRICAL REVIEW with advantage.

**The French Telephones and the State.**—The taking over of the French telephones by the State is leading to heavy outlay, and consequent discussion in the Chambers. Two supplementary credits are now asked for, one for 3,500,000 francs, and another of 1,629,622 francs, by the Ministry of Commerce, in order "to face the expenses of putting in order and extending the telephone lines."

**The Board of Trade Regulations.**—The electric lighting companies, says the *Financial Times* of Tuesday, have still a good deal to contend with at the hands of the Board of Trade. The report of Crompton and Company, Limited, thriving purveyors of electric light, mentions that a contract to light the town of Chelmsford has not been profitable, having "cost more than the original estimate, largely in consequence of unexpected and difficult requirements of the Board of Trade." "It is to be hoped that in the interests of science, of the great sum of capital invested in electric lighting companies, and of the public generally, this Chelmsford incident may be explained and thrashed out at the Crompton meeting next Monday." Perhaps our article on "State Control" may be the means of giving a helping hand to this end.

---

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

---

**Dermatine Company, Limited.**—The statutory return of this company, made up to the 8th August, 1889, was filed on the 27th ult. The nominal capital is £550,000 in £5 shares. 6,152 shares are taken up, and 7s. 6d. per share has been called thereon, £26,760 2s. 6d. is considered as paid upon 6,152 shares. The calls paid amount to £2,152 2s. 6d., and unpaid to £154 17s. 6d.

**Mutual Telephone Company, Limited.**—The statutory return of this company, made up to the 17th ult., was filed on the 8th inst. The nominal capital is £45,000 in £10 shares, 12 shares have been taken up, and £1 per share has been called and paid thereon. Registered office, 10, Tokenhouse Yard.

**Trent Gas Engine Company, Limited** (Gas Engineers and Electricians).—The statutory return of this company, made up to the 24th ult., was filed on the 28th ult. The nominal capital is £15,000, divided into 750 preference and 750 ordinary shares of £10 each. The shares taken up are 555 preference and 750 ordinary, 300 of the former and 750 of the latter being considered as paid up. Upon 255 preference shares, £7 10s. per share has been called, the calls paid amounting to £1,912 10s. Registered office, 38, Duke Street, New Basford, Nottingham.

**Archer Pipe Company, Limited** (Pipes and tubes for electric light, telephone, and other wires, &c.).—The statutory return of this company was filed on the 5th ult. The nominal capital is £10,000 in £1 shares. 8,672 shares are taken up, and of these 5,000 are considered fully paid. Upon 3,672 shares, the full amount has been called, the calls paid amounting to £3,467, and unpaid to £205.

### LEGAL.

**In re Northern Electric Wire and Cable Company, Limited.**—Chancery Division (before Mr. Justice Kay). This was a motion on behalf of Mr. Edward W. Hall, asking that the register of the company might be rectified by removing his name from the list of shareholders in respect of 160 £5 shares, and that his deposit money might be returned. Mr. Justice Kay said the facts were these:—On June 25th, 1889, the company was incorporated. Under the articles the subscribers to the memorandum were to be the temporary directors, until directors had been regularly appointed by the subscribers, or a majority of them. At 10.30 a.m. on June 25th, a meeting of the subscribers was held, at which four were present. A resolution was passed appointing directors, and also one allotting shares to different persons, amongst others, 160 shares to Mr. Hall. It was not until July 3rd that Mr. Hall applied for shares. On the 29th of July, another meeting was held, and the minutes of the previous meeting were passed. On the 14th of August, Hall told the secretary verbally that he would withdraw from the company. On the 23rd of August the secretary wrote a new letter of allotment. Upon this, Mr. Hall applied for a return of his deposit, but the directors in December forfeited his shares. Mr. Hall then brought this motion. In his Lordship's opinion there had been no allotment at all. There had been no application followed by an allotment, and a communication of that allotment to Mr. Hall; there had only been an allotment before application. The proceedings were most irregular, and the motion must be allowed, with costs.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Eastern Telegraph Company.

SIR JOHN PENDER, K.C.M.G., presided at the thirty-sixth half-yearly meeting of the shareholders, held at Winchester House on Thursday last, at 1 o'clock, when the following report, with the accounts for the half-year, was presented:—

The revenue for the period amounted to £424,023 14s. 3d., from which are deducted £98,477 16s. 3d. for the ordinary expenses and £47,520 2s. 11d. for expenditure relating to repairs, renewals of cables, &c., during the half-year. After providing £2,943 10s. 7d. for income tax, there remains a balance of £275,082 4s. 6d., to which is added £61,151 1s. 5d. brought from the preceding half-year, making a total available balance of £336,233 5s. 11d.

From this amount there have been paid:—Interest on debentures and debenture stock, £28,274 13s. 1d.; dividend on preference shares, £20,474 3d. 3d.; and an interim dividend of 1½ per cent. on the ordinary shares, £50,000; leaving a balance of £237,484 9s. 7d., from which £125,000 has been carried to general reserve.

The directors now recommend the declaration of a final dividend for the year ended March 31st, 1890, of 2s. 6d. per share and a bonus of 3s. per share, amounting together to £110,000 both payable on the 18th inst., free of income tax, and making, with the three previous payments on account, a total distribution of 13s. per share or 6½ per cent. for the year on the ordinary shares. The balance of £2,484 9s. 7d. shown at the foot of the revenue account is proposed to be carried forward to the next half-year.

The revenue includes £74,337 8s. dividend and bonus for the half-year upon the company's investments in the Eastern and South African, the Black Sea, the Direct Spanish and the African Direct Telegraph Companies.

The convention referred to at the last general meeting between the French Government and this company, for the renewal of the agreement for the direct line through France, and the landing and working of submarine cables at the company's station at Marseilles, has since been ratified, and the agreement has been renewed between H.M. Postmaster-General for a special wire by land line and cable connecting this line with London.

A convention has been entered into with the Italian Government for the prolongation for 20 years of the existing concessions, for the working and maintenance of submarine telegraph cables between Italy, Malta, Corfu and Egypt.

The directors have concluded an agreement with the Turkish Government for the laying of a short section of cable between the island of Perim and Sheikh Seyd, which will bring to this company's system the traffic from Hodeida Mocha, and other points on the coast of Arabia now being connected by the Turkish Government with their system of land lines to Jeddah.

The International Telegraph Conference has been held in Paris, at which the chairman, managing director, and other representatives of the company attended. The interests of the company were carefully watched, and the result has, been on the whole not unsatisfactory.

Sundry reductions in the Continental tariffs were made, to come into operation in July, 1891, which will affect the company's revenue to a moderate extent, but the directors hope that the increase of traffic will eventually recoup the loss.

Negotiations of an important character are being carried on between the Eastern Extension Company and the Australasian Colonies, with a view to effecting a large reduction in the tariff to Australasia. This company is interested in these negotiations in so far as it will take a part of the risk, trusting that the reduction of tariff will tend to a large increase of traffic, and it is believed that these negotiations will speedily be brought to a satisfactory conclusion.

The several sections of the company's cables are in good working order, with the exception of the original Red Sea cable, which connects Suakim with Suez and the Island of Perim. The frequent interruptions of this cable taken in connection with the prospect of increased traffic to Australia necessitates the laying of an additional cable in the Red Sea, from Suez to Aden, which the directors expect to have completed and in working order before the end of this year. The cost of this will be taken mainly from the reserve fund.

The Chairman, after explaining some items of the account, said:—On the last occasion he referred to the West Coast system as being fully completed, and that important results might be expected from it. He was now glad to confirm that opinion. One of their sections, the African Direct, was now paying 4 per cent., and he hoped in another year would see an increase upon that. The West African Company was paying a 5 per cent. dividend, and, if the state of things which had existed in Africa continued, they might also expect an increase in that quarter. Altogether they were in a position to meet all requirements which might arise in the development of the "Dark Continent." The company was prepared to do its part in connecting that new world with the old. The trouble which the company had recently experienced in Egypt had given place to a better state of things there, very much to the company's benefit. Its relations with Egypt were in fact most satisfactory. As regards the Telegraphic Conference, its attitude had been on the whole very fair to the cable companies, and this company's relations with European governments had never stood higher. It had had to submit to certain reductions in the interest of Spain, Portugal and Gibraltar, but he anticipated that these reductions would be compensated for by increased business. The company's relations with India were very materially improved at the conference. He further said that he had received a letter from a prominent shareholder, who, after complimenting the management generally, said that, looking to the large sum carried forward, a larger bonus ought to have been declared. He, the chairman, observed, with regard to that, that the company was party to an arrangement with the Eastern Extension Company, whereby the tariff with the Australasian companies was to be reduced from 9s. 4d. to 4s. a word. They had, however, the guarantee of the Governments of those colonies that the companies should not receive less money than they received in 1890. These reductions in tariff must necessarily lead to a very great extension of the system generally. The company's Red Sea cables had been in operation for nearly 20 years, and the directors would not do their duty to the company or the public if they neglected to prepare at once for this increase of traffic. They had, therefore, decided to lay another cable from Suez to Aden, which must cost at least £250,000. With a view to maintaining the respectable dividends which the company now paid, the directors thought it better to pay for that cable at once, and he thought their policy was better conducive to the value of the shareholders' property than by adding to the capital now and eventually reducing the dividends. He moved the adoption of the report and accounts, and to declare a dividend on the preference shares to 30th June, 1890, at the rate of 6 per cent. per annum (less income tax), and a further dividend of 2s. 6d. per share, with a bonus of 3s. per share (free of income tax), on the company's ordinary shares, making, with the previous payments on account, a total of 6½ per cent. on those shares for the year ending March 31st, 1890.

The Marquis of Tweeddale seconded the motion.

Mr. Parsons, a shareholder, assailed the policy of the board, and said that had the company been directed by a body of practical

men, the dividends would have been very much larger. His opinions, however, were apparently not shared by the meeting.

The Chairman thought the meeting would share his contempt for the very remarkable jumble of ideas and ancient history they had just heard, coming, as it did, from one who should know better, he having been some fifteen years ago in the company's service. He, the chairman, had never listened to a greater display of vindictiveness with so little reason.

Mr. Parsons, on rising to make some further observations, was peremptorily informed that he could not be heard.

Mr. J. Gibb then moved a resolution, in which the shareholders expressed their sincere sympathy with Sir John Pender and his family in their present affliction, and which was carried unanimously.

Another Shareholder moved an expression of the obligation which the shareholders felt themselves to be under to Sir John Pender, Sir James Anderson, and other members of the board for their efforts in connection with the Telegraphic Conference, and, with a vote of thanks to the board for its conduct of the company's business generally, the meeting came to an end.

### The Elmore Wire Manufacturing Company, Limited.

MR. GEORGE SMITH, chairman of the Kent Waterworks Company, presided, in the absence of Sir John Morris, at the first general meeting of the company, held at the Cannon Street Hotel on the 14th inst. He explained that it was a formal statutory meeting without report and accounts. But as the shareholders might desire to know what the directors had been doing in the four months of the company's existence, he went on to say—First, as to the subscribed capital: Notwithstanding the adverse state of the financial world at the time of the launching of the company, about 500 applicants had subscribed for shares, and an ample allotment had been made to carry on the company's business. Secondly, as to the company's relations with the Stock Exchange: Application had been made for a quotation and a settlement, and, upon the shareholders agreeing to the proposed alteration in the articles which the Stock Exchange required, the company would doubtless have its application granted. A special meeting would be held for that purpose. Thirdly, as to the land acquired: 12 acres of freehold land had been secured adjacent to the parent company's works at Haigh Park, Leeds, and manufacturing buildings had been erected there under the responsible supervision and control of the company's managers. Fourthly, as to plant: Orders had been given for plant, and would be followed up judiciously until the factories are completed and set to work, which, it was anticipated, would be before the close of the year. The directors' arrangements, with regard to the company's works, had been influenced by the consideration of the many advantages of having them contiguous to those of the parent company, whereby the company would be in a position to share with the parent company the services of the Messrs. Elmore, and so economise an important item of its working expenses, whilst it would secure the presence of Messrs. Elmore always at hand. Fifthly, as to the company's policy: The policy which the directors had elected to follow had been to work with, rather than against, the wire manufacturing trade, and they were happy to be able to say that a very substantial group of Birmingham wire-drawers had offered to take the whole of the company's output of spirals for 1891, with prospective arrangements for continuing the agreement at a price which would yield substantial results to the company. The advantages of such an arrangement were many and obvious. First, the company secured an established trade for all it could make without having to create a trade; secondly, the company enlisted the interested co-operation of some of the most important manufacturers of wire in the company, instead of having them for rivals; thirdly, it avoided bad debts, the firms in question being of the highest standing; and fourthly, the company was released from capital expenditure for wire drawing, and thereby enabled to lay down more deposit plant, and to simplify and increase its business. The terms had been approved, and the agreements would shortly be executed and exchanged by the parties. The directors therefore felt they might congratulate the shareholders of the company upon the prospects before them. Those of them who might wish to see specimens of the manufactures of this depositing process would find them exhibited at 56, Queen Victoria Street, and would do well to inspect them.

An extraordinary meeting was held immediately after the close of the above general meeting, when the following resolution was proposed by Mr. Smith, chairman, and seconded by Mr. Carson:—

"That the following clause be substituted for Clause 80 of this company's articles of association:—

"The company may make contracts with any of the directors upon such terms as the directors shall think fit, and a director shall not by reason of the fiduciary relation subsisting between him and the company be accountable for any profits made by him in respect of any such contract, nor, subject to the following proviso, in respect of any other contract made with the company in the profits of which he participates, or in which he is otherwise interested, provided that the fact of his being so interested therein, and the nature of his interest, be fully and fairly disclosed by him at the meeting of the directors at which the contract is determined on, if his interest then exists, or in any other case at the first meeting of directors after the acquisition of his interest; but in the case of contracts with companies or firms of

which any director of this company is a member, it shall not be necessary to disclose more than the fact of such membership, provided always that in no case shall such director so interested vote, or, if he does vote, his vote shall not be counted."

The Chairman explained that the resolution will be submitted for confirmation as a special resolution at a second extraordinary general meeting, of which due notice will be given.

The Company's Solicitor explained that the proposed alteration of the articles of association is necessary in order to comply with the requirements of the Stock Exchange Committee, before that body will give this company a special settlement and official quotation of its shares.

The resolution was agreed to unanimously, and the proceedings terminated.

### National Telephone Company, Limited.

THE tenth ordinary general meeting of the shareholders was held at the City Terminus Hotel, Cannon Street, E.C., on Friday, the 11th inst., at 12 o'clock, to receive and adopt the report of the directors and the accounts for the year ending 30th April, 1890 (printed in our last issue).

The Chairman, Mr. F. R. Leyland, said that the whole of the amalgamation expenses, by which he meant the Government tax on the increased capital, and the tax on the transfer from the United, and Lancashire and Cheshire Companies, had been included in the year's accounts. The directors had acted on the principle that everything that could be possibly included in the expenses of the year should be so included and paid out of the year's earnings; and, in distinguishing between capital and revenue expenditure, the directors had, in the absence of any doubt, thought it desirable to err on the side of leaving the capital as little augmented as possible. Perhaps the most important consideration was contained in the recommendation made in concluding lines of paragraph I. of the report. That recommendation was made very much upon the same lines and policy as had been pursued in making up the accounts. The directors thought it desirable, now they had a year at least before them, to strengthen their position by adding to the reserves and declaring only a moderate dividend. Six per cent. was not an unsatisfactory dividend. They had to face the fact that competition might arise. They knew that one competing company had already been formed in Manchester. Fortunately it was not a very strong one, and it had a good deal to learn, as they would find. The patent which would be the first to expire was the Bell receiver, which would expire in December. He had been told that it would be utterly impossible for the competing company to carry on its business as it said at the expiration of that time. The patent might be used for a small exchange with advantage, but would be impossible in a large exchange. Their competitor would have to wait until the second patent, viz., the transmitter, expired in July, 1891. But even then there would be other patents which did not expire until 1893, and were all of material advantage to a good service. Letters had appeared from time to time in the Press, from the Mutual Company and others not connected with it, but apparently taking a very great interest in telephone matters; and, more especially, there was the speech of the Duke of Marlborough in the House of Lords; the statements contained in them all seemed to be founded on the assertion that the telephone service abroad could be done for very little—something like £4 6s. 8d. per subscriber—the charge made in Norway, in Sweden. How could they possibly compare Stockholm and Christiania with London, Manchester, Liverpool, Glasgow, &c.? Then, a large item in the construction account was for poles for carrying the wires. In Norway and Sweden they had these poles on the spot. There was also the relative cost of labour to be considered. Then companies in Norway and Sweden were not subjected to a tax of 10 per cent. on their gross income. Foreign companies were not required to pay for way leaves, whereas the amount which the company had to pay for way leaves was £25,000 per annum. The Duke of Marlborough said that in Paris there were three or four times as many subscribers to telephones as in London. The fact was, there were 7,800 subscribers in Paris, and 5,800 in London. That was a sample of the reckless statements that were made outside. The Duke also said that the charge for the telephone in London was £20 a-year, whereas the average charge in all continental capitals was only £6. Let them take Paris. The companies there used to charge £24. The Government took over the telephones, and, having no desire to make a profit, reduced the charge to £16. They must go a long way among European capitals to get anything like an average of £6, when they commenced at £16. In the French provinces subscribers had to buy their own apparatus and pay the cost of the wire as well. In Berlin, and throughout Germany, an average charge was made all round of £7 10s.; but then there was no 10 per cent. payable to the Government, no cost of way leaves. The Government might fix the standard on your house-top or in front of your door—whether you liked it or not. In Madrid the charge was £12; St. Petersburg, £23 2s. 6d.; Sweden and Norway, £4 8s. 10d. and £4 8s. 1d.; but in these countries they only allowed you a certain number of conversations in the year, and charged you an extra amount for every conversation above that number. In New York they charged £30 to £36; Boston, £19 to £24; Chicago, £25; Pittsburg, £16 16s. to £20; Washington, £12, £16 and £20, according to distance; New Orleans, £19 15s.; Philadelphia, £24. As regards dealing with competition there would be no relinquishment of the company's position, and all measures necessary to strengthen it, and to keep the field, for it would be

taken. Economy of working and efficiency of service were most important considerations. Efficiency of service had been the first to engage the directors' attention. They had found, in London especially, that a great many of the switchboards were of an antiquated pattern. These had all been replaced with the exception of two. Then they had had to deal with the junction wires. One of the greatest defects of the London system had been the multiplicity of these exchanges. These had been considerably reduced, in the City especially, and the reduction would be continued until, if possible, the whole was got into one or two exchanges. The junction wires had been improved and looped to the extent of 350 miles, and there were 1,200 still to be done. Some 1,700 of the instruments had been fitted with magnetos, leaving about 350 to be done, and various other improvements had been made. To have done more than had been done would have involved a serious stoppage of the service. As regards the trunk line to the North he was very pleased to be able to tell them that they had at last got into communication with Manchester, Liverpool and Birmingham. The trunk lines would be one of their great standbys in competition. They were now pretty well all over the country. They had all been profitable, *i.e.*, they returned a fair interest for money expended. They had now a larger business being carried on at practically the price for which they had formerly carried on a much less important one, and he had no doubt that next year they would have a better report—certainly one as good. They must, however, take the labour difficulty into account. Everyone was asking for an increase in wages. The taking over of the Northern District Telephone, completed about a month ago, was, he thought, a wise thing for themselves, and he was sure a necessary thing for the Northern Company. It saved considerably in the working expenses, and secured a promptness of decision on the part of the board which could not be when they had three separate boards. The policy of the amalgamated companies was to include the South of England and the Western Counties, the only two counties now outside the amalgamation. That was, however, a question of price. The number of proxies sent in, *viz.*, 81,788 shares out of 468,984, was a substantial expression of opinion in favour of the board. He had recently received a letter from a very important shareholder, and one who had considerable experience in financial matters, on the question of dealing with the reserve fund. The writer appeared to be in favour of investing it in marketable securities. If so, they ought also to invest in securities in which there was not a large fluctuation in price. But in that case, there was little chance of more than a very low interest. Where was the policy of investing money which would not give more than 3 per cent. and borrowing money for the purpose of extending capital, paying 4 per cent. for it at the least. At present the reserve was being largely employed in buying up the Northern District. The old shareholders were given the choice of payment in the company's ordinary shares, or in sovereigns. They chose the latter, whereby the company made a better bargain. The policy of the board would be a big reserve and a moderate dividend. He moved that a dividend at the rate of 6 per cent. per annum (less income tax) on the first and second preference shares, and on the fully paid ordinary shares (excluding the 52,109 new ordinary) be paid for the half-year ending 30th April last, making, with the interim dividend already paid, a total dividend of 6 per cent. for the year.

Mr. J. S. Forbes seconded the motion, which was carried unanimously. Messrs. Welton, Jones & Co. were reappointed auditors, and with a vote of thanks to the board, the meeting came to an end.

### United River Plate Telephone Company, Limited.

The report of the directors to be presented to the shareholders at the fourth ordinary general meeting to be held at Winchester House, 50, Old Broad Street, E.C., on Tuesday, the 22nd July, 1890, at 12 o'clock noon, states the result of the company's operations during the year ending 31st March last, after paying all working expenses abroad, debenture interest, London and other charges, is a profit of £34,198 6s. 5d., from which has to be deducted the sum of £22,334 17s. 1d. for loss on exchange, leaving a net profit of £11,863 9s. 4d., increased by the balance of £1,210 7s. 2d. brought forward from the previous year, to £13,073 16s. 6d. Out of this, an interim dividend of 2 per cent., or £5,800, was paid in January last; and the directors recommend that out of the remaining balance of £7,273 16s. 6d., a further dividend of 1 per cent., or 1s. per share, free of income tax, be now paid, which absorbs £2,900; that £2,000 be placed to the depreciation and renewal fund, thereby increasing it to £9,000; and that the balance of £2,373 16s. 6d. be carried forward to the credit of profit and loss account for the current year. As shown in the balance sheet annexed, the capital expenditure during the year amounted to £12,772 8s., as against £35,070 2s. 11d. in the previous twelve months. The business of the company has largely increased during the past year, the gross receipts having been £108,612 2s. 7d., as compared with £81,866 2s. 4d. in the year before; such a development of business has necessarily increased the working expenses in the River Plate, and the continued depreciation in the currency there has naturally given rise to a necessity for higher wages. In spite of these difficulties, the result of the company's working would have been very satisfactory but for the serious increase (more especially during the second half-year) in the loss on exchange, which amounted to £22,334 17s. 1d., as against £14,689 6s. 8d. in the previous year, the net profits having been thereby so reduced as to make it impossible for the

directors to recommend so high a dividend as last year. But to meet this loss on exchange to some extent, the directors raised the rates of subscription on the 1st January last, and they are glad to say that the change has been carried out successfully. The shareholders will remember that the directors were authorised at an extraordinary general meeting held on the 9th January this year to issue debenture stock and convert the then existing 7 per cent. debentures; and the directors are glad to report that out of £100,000 7 per cent. debentures, £97,000 have been converted into 5 per cent. debenture stock, and that £29,000 of the same stock, offered to the shareholders, was largely over-subscribed. Under the articles of association, the Right Hon. Lord Thurlow and Mr. Frederick Green retire by rotation at this meeting, but, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. & Co., also retire, but offer themselves for re-election.

### Crompton and Company, Limited.

THE second report of the directors, to be presented at the annual general meeting of the shareholders at the City Terminus Hotel, Cannon Street, in the City of London, on Monday, the 21st July, 1890, at 2.30 o'clock, p.m., states:—The net profits for the year amount to £10,610 1s. 7d., and after payment of the interim dividend last December, and providing for debenture interest and other payments set out in the accounts, there remains a balance of £6,030 6s., from which the directors propose, after setting aside a sum of £500 as a provision for doubtful debts and contingencies, to declare the usual dividend of 7 per cent. per annum upon the preference shares, and 5 per cent. per annum upon the ordinary shares, carrying the balance forward. The business of the company has greatly increased, necessitating considerable extension of the works, and large additions to plant. The contract for the public lighting of Chelmsford has been carried out, and the result has given great satisfaction in the town. It is hoped that private consumers will now apply for the light in sufficient numbers to make the contract a profitable one. The installation has cost more than the original estimate, largely in consequence of unexpected and difficult requirements of the Board of Trade. Very important contracts have been arranged with several of the electric supply companies in London, the principal feature of which is that this company receives a fixed profit upon the actual cost of the works, and large orders are also in hand for other companies and firms, the prospects of the present year being in consequence very good. It is with the greatest regret that the directors have to record the loss, by death, in October last, of Viscount Torrington, the chairman of the company. In accordance with the articles of association, Sir Charles Grant retires from the Board of directors by rotation, but offers himself for re-election. The auditors, Messrs. J. H. Duncan & Co., also offer themselves for re-election.

### The Direct United States Cable Company, Limited.

—The board has resolved to recommend a final dividend of 3s. 6d. per share, free of income tax, such dividend to be payable on and after the 26th instant, making, with the interim dividends already paid, 3½ per cent. for the year ending 30th June last, carrying forward £968 0s. 3d., after having transferred to the reserve fund account £8,502 14s. 5d., making it up to £250,000. Notice is also given that the transfer books of this company will be closed from the 11th to the 25th July, both days inclusive.

**The Edison and Swan United Electric Light Company, Limited.**—The directors announce a dividend at the rate of 7 per cent. per annum on the "A" shares for the half-year ended the 30th ult. (making 7 per cent. for the year), and a further dividend of 4 per cent. in completion of payment of arrears of cumulative preference dividend for the year ended June, 1884, and a further dividend of 4 per cent. in respect of arrears of cumulative preference dividend for the year ended June, 1885.

**Parker's Electric Wire Corporation, Limited.**—A general meeting of the members of this company will be held in Temple Chambers, Temple Avenue, London, E.C., on the 12th August, at 4 p.m., when an account will be produced of the winding up of the company, and other business transacted.

**MacNabon's Electric Automatic Registering Company, Limited.**—A general meeting of the shareholders will be held at the office of the liquidator, Mr. Wm. G. Jefferys, 53, Coleman Street, London, E.C., on the 18th August next, when the liquidator's accounts will be produced.

**The Globe Telegraph and Trust Company, Limited.**—The directors propose a final dividend of 4s. 3d. per share, making 5 per cent. for the year ending the 18th inst., a balance of £108 being carried forward.

**The Edison Electric Illuminating Company, New York,** has declared a quarterly dividend of 1 per cent., payable August 1st.

### TRAFFIC RECEIPTS

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending July 14th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,644.

ELECTRIC LIGHTING AND COUNTY  
COUNCIL.

## PROVISIONAL ORDERS FOR NEXT SESSION.

At the meeting of the London County Council on Tuesday last at Spring Gardens, under the presidency of Sir John Lubbock, Mr. T. B. Westacott (the chairman of the Highways Committee) presented a report, which stated, for the information of the Council, that the following notices of intended applications next session for provisional orders under the Electric Lighting Acts had been received:—

Undertakers.	Areas of Supply.
St. James and Pall Mall Electric Lighting Company.	Parishes of St. James, Westminster; and St. George, Hanover Square.
Brush Electrical Engineering Company.	Parishes of Fulham, Hammersmith, Islington, Shoreditch, St. Luke, Clerkenwell, Bethnal Green, and Districts of Hackney and St. Saviour.
Laing, Wharton and Down Syndicate.	City of London (east and west districts); Parishes of Shoreditch and Islington; and Districts of Hackney and Whitechapel.
Westminster Electric Supply Corporation.	Parishes of Paddington, Chelsea, St. Marylebone, Kensington, and St. Margaret and St. John, Westminster (part of).
New Cadogan and Belgrave Electric Supply Company.	Parish of St. George, Hanover Square.
Ditto ditto	Parish of Chelsea.
London Electric Supply Corporation.	Area not specified.
Metropolitan Electric Supply Company.	Ditto

## LONDON ELECTRIC SUPPLY CORPORATION.

The same committee reported that they had considered a notice from the London Electric Supply Corporation (with one plan) of intention to lay trunk mains in Stamford Street, York Road, Sutton Street, and Belvedere Road; together with a letter from the company asking that, as it had arranged a new route for its mains, this notice might be taken in substitution for that dated April 18th, 1890, the works referred to in which were approved by the council on May 1st last. "The council will probably not think it desirable to interfere with the discretion of the company with reference to the route to be adopted for its trunk mains; but your committee think that, in order to obviate the necessity of a second interference with the same streets, the company should be required to lay its distributing mains at the same time as the trunk mains. Your committee therefore recommend:—That the sanction of the council be given to the works referred to in the notice (Registered No. 96) of the London Electric Supply Corporation, dated June 19th, 1890, upon the following conditions:—That the distributing mains be laid at the same time as the trunk mains, in order to avoid a second interference with the same streets; that the mains be protected from injury by a sufficient outer covering, to the satisfaction of the council's engineer; and that the company do give three days' notice to him before commencing the work in any of the thoroughfares referred to in the notice."

The same company had also asked for the consent of the council to an alteration of the route of its mains in Cockspur Street, from the south side, as shown upon the plan submitted with the notice dated June 4th, 1890, sanctioned by the council on June 24th last, to the north side of that street. "This alteration, which is shown upon a plan submitted by the company, requires to be made in order to meet the wishes of the Postmaster-General; and your committee, seeing no objection to it, recommend:—That the Council do consent to the alteration of the route of the London Electric Supply Corporation's mains in Cockspur Street (referred to in the notice Registered No. 90), as shown upon the plan submitted by the company."

Both these recommendations of the committee were approved by the council.

## MISCELLANEOUS.

The Highways Committee further reported that they had considered a letter from the Board of Trade, forwarding, for the observations of the council, a copy of an application from Messrs. Woodhouse and Rawson United, Limited, for permission to purchase from the West Middlesex Electric Lighting Company the undertaking authorised by the Fulham District Electric Lighting Order, 1884, which order was revoked by the board in October last. This order did not, of course, contain the provisions conferring powers upon the council, introduced last year for the first time into electric lighting orders relative to the County of London, and the committee did not consider that it would be desirable to revive an order of the old form, unless it could be brought into conformity with those of last year. They therefore recommended, and the council resolved, as follows:—"That the Board of Trade be informed that in the opinion of the council the permission asked for by Messrs. Woodhouse and Rawson United, Limited, should not be granted, unless the provisions of the Fulham District Electric Lighting Order, 1884, be so modified as to make them accord with the orders recently granted by the board."

Mr. JOHN HUTTON, as chairman of the Building Act Committee, submitted their report, which made the following, among other recommendations, which was agreed to:—"That the application of Mr. E. Garcke, on behalf of the Brush Electrical Engineering Company, Limited, for approval of a plan for the construction of an addition to a temporary iron building in Belvedere Road be not granted, as the committee consider it undesirable to sanction the erection of any additional temporary structure at the premises in question."

## BARNSELEY AND ELECTRIC LIGHTING.

MR. J. H. TAYLOR, borough surveyor, has prepared a report on the proposed electric lighting of Barnsley. The report gives the results of the labours of the Park and Lighting Committee of the Barnsley Town Council in the matter, they having had it under consideration for almost a year past. It states that tenders were invited, but the "high charges and excessive terms of purchase asked by the companies" were such that they were compelled to relinquish all ideas of introducing the electric light to Barnsley by the medium of a private company. The committee then invited tenders for the supply and erection of a complete plant for lighting with electricity the streets, roads, and other places within what is called the inner area, and which practically comprises the whole of the business portion of the town, and also for lighting 5,000 10-candle-power lamps, or their equivalent in arc and incandescent lamps, in buildings within the inner area. The corporation in this case is to provide the buildings, the contractor to provide and build the foundations for all engines, dynamos, and boilers, and to lay out the plant in the best manner of extending the same, so that eventually the whole of the borough may be lighted from the central electric lighting station, appliances to be provided for supplying 50 arc lamps of 1,200 candle-power each; 142 incandescent lamps of 32 candle-power each; and 5,000 lamps of 10 candle-power each, or their equivalent in arc and incandescent lamps, and with one engine and boiler, and one each of the arc and incandescent light dynamos to spare. Lamps and posts for 50 arc lamps and 140 incandescent lamps are to be provided of ornamental design in iron; the cables and wires of copper properly insulated and erected overhead. The necessary precautions for the proper carrying out of these tenders are taken. In response to these proposals tenders were obtained from several companies. The Gülcher (New) Electric Light and Power Company, Limited, offer to do the work for £25,500, subject to a reduction of £2,000 if bare copper mains are used. The Electric Construction Corporation, Limited, submits two tenders—one of £22,751, and the other of £21,721. The Manchester Edison-Swan Company, Limited, tender to do the work for £19,200, or for £2,000 less if the cable supports are made partially or entirely of wood. The other tenders are:—Westinghouse Electric Company, Limited, £17,800; Laing, Wharton and Down Construction Syndicate, Limited, £16,975; Brush Electrical Engineering Company, Limited, £13,100; and National Electric Supply Company, Limited, £11,888. On these tenders and the whole scheme proposed for the electric lighting of the borough, Mr. A. Bromley Holmes, electrical engineer, of Liverpool, was consulted, and he recommended the adoption of the "high tension alternating system" as the best and most suitable for a town like Barnsley, and after giving his reasons against the proposals of the other companies, so far as Barnsley is concerned, recommends that of the Westinghouse Electric Company, Limited, £17,800, as the most favourable. In a subsequent report, Mr. Holmes states that he has inspected the Westinghouse installation at Sardinia Street, London, made by the company for the Metropolitan Electric Supply Company, Limited, and finds the arrangement simple and practical, the plant well designed and constructed, and working in a perfectly satisfactory manner. Certain modifications suggested in the original tender have been agreed to by the company, and Mr. Holmes says he can now recommend its acceptance, and adds that in the estimate of capital expenditure it would be well to add £700 for mechanical stokers on the boilers, and for additional transformers, making a total of £18,500. He submits an approximate estimate of such a station for Barnsley, as follows:—Cost of water, oil, waste, &c., £1,450; renewal of carbons and street incandescents, £225; salary of chief engineer and assistant, £350; wages of enginemen, stokers, linemen, and labourers, £936; collector and clerk's assistance, £200; sundry expenses, £200—£3,361. Interest, sinking fund (five per cent. on cost of site and buildings, £4,000), £200; 10 per cent. on cost of plant, &c., including repairs (£18,500), £1,850—£2,050; making a total estimated annual cost of £5,411. Mr. Holmes adds:—"Assuming the 5,000 ten candle-power incandescent lamps to be used on the average 800 hours per annum, each lamp would consume approximately 32 units of electricity, which, if sold at 6d. per unit, would bring in a revenue of £4,000. Deducting this sum received for private lighting from the working costs given above, would leave a balance of £1,411 as against the street lighting. The street arc and incandescent lamps would replace 248 gas lamps, giving a total light of 6,574 candles, costing £800 per annum. The 50 arc and 140 street incandescent lamps would give a total light of 54,480 candles. The cost of extending beyond the inner area would probably be £50 for each arc lamp and £10 for each 32 candle-power incandescent lamp." On these facts and figures the committee recommend that the tender be accepted of the Westinghouse Electric Company.

## REVIEWS.

*Derivation of Practical Units.* By Lieut. F. B. BADT and Prof. H. S. CARHART. Electrician Publishing Company : Chicago, U.S.A.

This small work is mainly a reprint of articles published in the *Western Electrician*. Its title, though it no doubt is, strictly speaking, correct, is, we think, very liable to be misleading, as the book is not a scientific treatise on electrical units, but a series of short illustrated biographies of famous electricians to whom the system of electrical units is practically due and by whose names the units are designated. A final chapter by Prof. Carhart deals briefly with modifications of the practical units.

*Inventions and How to Patent Them. A Practical Guide to Patentees.* By EUSTACE SMITH. Third Edition. Revised. London: Whittaker & Co., Paternoster Square.

This is an exceedingly handy and useful little volume, and should be possessed by all who are interested in the subject. The sections into which the work is divided are as follows:—What is a Patent? What Inventions can be Protected by a Patent? When is a Patent New? When is a Patent Useful? What amount of Invention is Necessary to Support a Patent? Who may apply for a Patent? How to obtain a Patent; Dealings with Patents; Retention of Patents; Information on Practical Points.

*Journal of the Institution of Electrical Engineers.* No. 87. London: E. & F. N. Spon, 125, Strand.

The contents of this number are as follows: "On Signalling across Rivers in India," by W. F. Melhuish; "The Diathermancy of Air in Relation to the Efficiency of Incandescent Lamps," by F. Higgins; "On Lightning Guards for Telegraphic Purposes, and on the Protection of Cables from Lightning," by Oliver J. Lodge; Original communications, Abstracts, &c.

## ALTERNATING CURRENT MOTOR.

THE accompanying cut from an American exchange, illustrates diagrammatically an alternating current motor, recently patented by Elihu Thomson, of Lynn, Mass. Rotation in this motor is due to the reaction between an alternating current field and a locally short-circuited armature. These motors, when running at normal speed, are capable of sustaining speed in synchronism, or nearly in synchronism, with the alternations of the feeding wire, but are incapable of starting.

The invention consists in commencing to run the motor with a different circuit arrangement for its armature from that which it will have under the condition of steady normal working. This primary condition is one adapted to give a torque. When up to speed the motor is run with the armature on continually-closed circuit.

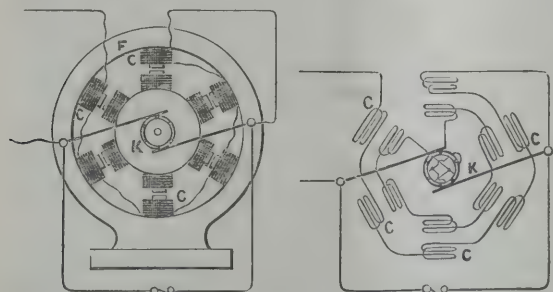

FIG. 1.

FIG. 2.

In the accompanying cuts, fig. 1 is a side elevation of a form of motor to which the invention may be applied. Fig. 2 is a diagram of the circuits and connections of the apparatus. In the figures, F represents a laminated field magnet frame having projections upon which are

wound coils, C, as many as six in number. These projections extend inwardly toward a revolving laminated armature. Upon the shaft of the machine is a commutator, K, consisting of six segments, each alternate segment being connected, so that there are in reality but two divisions of three segments, each fitted together. The armature coils are so connected that if a continuous current were passed through the coils the projections on the armature would assume alternately north and south polarities. The field coils are connected in a like manner. Now if an alternating current be passed through the field coils, C, the motor will not start to rotate whether its armature circuit be practically open, or whether the coils be on closed circuit; but it will continue to rotate in either direction if it is once started, if the armature coils are placed on closed circuit, and the current fed to the coils, C, has sufficient energy. In the motor shown, the alternating current which passes through the field is made at the start to circulate through the armature. In the initial condition of the motor the brushes are set backward or forward into proper position, where the armature will begin to rotate. When a certain speed has been obtained, the motor is made to assume its normal working condition and to continue its rotation without the commutator by short-circuiting the armature by any desired means. These changes of condition may be made by devices manually operated; but the inventor prefers to bring them about automatically by the operation of some device responsive to the change of speed of the armature.

## ACTION OF LIGHTNING UPON THE HUMAN ORGANISM.

ACCORDING to Vienna papers of the 4th inst. Prof. Nothnagel, in his clinical lectures, yesterday exhibited to his hearers a young woman, aged 20, Josepha Schleser, who had been recently struck by lightning in Styria, and had come to Vienna for treatment in Prof. Nothnagel's hospital. The patient suffered from a derangement of the nervous system. To his remarks on this case the lecturer added a discourse on the effects of lightning, substantially as follows: Formerly it was known merely that the burns occasioned by lightning had a zigzag figure, and that the further consequences might be paralysis or death. During the last ten years the lecturer had made comprehensive experiments upon rabbits with the electric spark of a large Leyden jar, and has thrown a new light upon this question. The action of lightning upon the brain, the spinal column and the peripheric nerves is shown by the loss of consciousness, the disturbance of the intellect, and the extended phenomena of lameness, the latter of which have a tendency to disappear. On the other hand, there are intense nervous phenomena which strongly resemble those produced by railway accidents and other concussions, and which dominate the patient for a long time. Disturbances of sight and speech often occur, and may remain for life, or may in part disappear. In other cases there may be observed in the person struck a childish frame of mind which may incline either to reckless merriment or to sadness and melancholy. Experience proves that lightning produces its chief effects only at the points of its entrance and exit. Thus a flash which entered a schoolroom injured only the first and last child on the form, those between escaping unhurt. Prof. Nothnagel pointed out that in the treatment of lameness and other constitutional perturbations due to lightning metallotherapy is most efficient, a large horseshoe magnet being applied alternately to the head, trunk and the limbs. This process led to better results than the electric treatment recently adopted. In case of a quite recent stroke the clothing should be unfastened, the patient laid with the head high, quietness and fresh air should be secured, and if consciousness does not return the head should be exposed to a stream of cold water.

PROCEEDINGS OF SOCIETIES.

The Institution of Electrical Engineers.

"The Working Efficiency of Secondary Cells." By W. E. AYRTON; C. G. LAMB, E. W. SMITH and M. W. WOODS, Associates. Read at Edinburgh, Wednesday, July 16th.

I.—PREVIOUS TESTS OF CELLS.

Since 1881, when the formation of Planté storage cells was greatly accelerated by Faure's device of pasting the plates, numerous tests have been made in different parts of the world on the capacity and efficiency of secondary cells. The first tests that were carried out were conducted simultaneously, at the end of 1881, in England by Prof. Perry, with one of the authors of this paper, and in France by a committee consisting of Messieurs Tresca, Potier, Joubert and Allard, working at the Conservatoire des Arts at Metiers, with a staff of assistants.

In the report—communicated to the Physical Society in February, 1882—by the two English experimenters, it was pointed out that the great "resuscitating power" of the cells made it very difficult to say when they were entirely discharged, and therefore, in order to test the efficiency, the cells were first "emptied" of charge by discharging them until the discharge current was very small, and finally leaving them short-circuited for many hours with a short bit of thick wire. Next, a measured amount of energy was put into these "empty" cells, and they were then thoroughly discharged on three successive days, being insulated and allowed to recuperate during the two intervening nights. Although the energy efficiency thus obtained, and which was not less than 82 per cent., probably represented much more than could be obtained in practice at that period, if the discharge were stopped before the E.M.F. fell to so low a value, this efficiency represented something quite definite, since all the energy given out by the cells in the discharge must have been put into them during the measured charge, no demand being made on some inexhausted store of energy previously put into the cells.

The French committee, on the other hand, considered the cells as being discharged when a certain current which was originally produced through a fixed resistance by 30 cells could no longer be kept up, even when the number of cells had been increased to 35. But unless, subsequently to the receipt of the cells from the manufacturers, they had been charged and discharged several times until the same cycles of values of E.M.F. with time were repeated with each charge and discharge, there was no guarantee that in the experimental discharge the cells were not drawing on a store of energy put into them before leaving the manufacturers' premises, and thus giving a higher value than the "working efficiency."

And we are afraid that a very possible neglect of the powerful resuscitating power of accumulators may have vitiated some of

the published results of experiments that have been made on them. This doubt must not be forgotten in considering the accompanying list, which is as complete as we have been able to make it, of all such experiments that have been made up to date. At the middle of 1889, when we had nearly completed our investigation, there appeared two very important contributions to the subject—one on "The Inherent Defects of Secondary Batteries," by Dr. Louis Duncan and H. Wiegand; the other, "Ergebnisse von Versuchen an Akkumulatoren für Stationsbetrieb," by Prof. W. Kohlrausch and C. Heim. These investigations are extremely interesting, as they confirm some of the results which we had also arrived at, and to which reference will be made in this paper; Prof. W. Kohlrausch and C. Heim, for example, laying great stress on the fact that the discharge of an accumulator does not depend merely on the previous charge, but on the previous history of the cell.

At the Central Institution there are three distinct types of E.P.S. cells in daily use. The cells, however, used by us for the investigation were 20 out of a group of 50 of what is known as the 1888 type. This type we selected since it was the latest constructed by the Electrical Power Storage Company. The particular specimens of this 1888 type, which are at the Central Institution, contain each two positive and three negative plates, each plate, exclusive of the lugs, being 9½ by 9½ inches. The glass vessels containing these plates are large enough to each hold 7L plates, but we preferred to use 7L glass boxes to having smaller boxes specially constructed.

The total weight of each of these cells is about 59 lbs. 12 oz., made up as follows:—

	lbs.	oz.
3 negative plates ... ..	about	17 2
2 positive " " " " " "	"	11 8
Ebonite strips ... ..	"	0 8
1 glass vessel ... ..	"	7 8
Dilute sulphuric acid ... ..	"	23 2

and the cells are intended to be used with a maximum current of 9 amperes on charging and 10 on discharging.

The first point to settle with reference to the discharge was whether the resistance in the circuit should be kept constant, or whether as the E.M.F. fell the resistance should be varied in such a way as to keep the current constant. This latter method, although it involved much more labour, was adopted. At first the current was kept constant by varying the resistance by hand as the E.M.F. of the cells altered. But this required the constant presence of one of the observers day and night, partly to vary the resistance from time to time, and partly to start the charging directly the discharging was finished, in order that the cells might never be left discharged. Hence an automatic arrangement, which will be described later on, was subsequently devised, and by means of it the current was maintained more constant than could be achieved by even very careful hand

regulation, and the circuit broken during discharging and during charging the moment the P.D. reached certain pre-arranged values.

We had next to adopt a criterion by which to settle when a charge or discharge could be said to be completed. Such a criterion may be made to depend on a variety of changes that take place in a cell, three of which are in common use—viz., change in the specific gravity, gassing, and change in the P.D. In the case of the cells tested by us, and which have more liquid in proportion to the plates than is usually the case, the change in specific gravity from charge to discharge is from 1.2 to about 1.17; and, as our experiments show that the change is directly proportional to the time, when the current is kept constant, the change in the specific gravity per hour is only about 0.002, which

Potential difference per cell, charging with 9 ampères. End of charge.

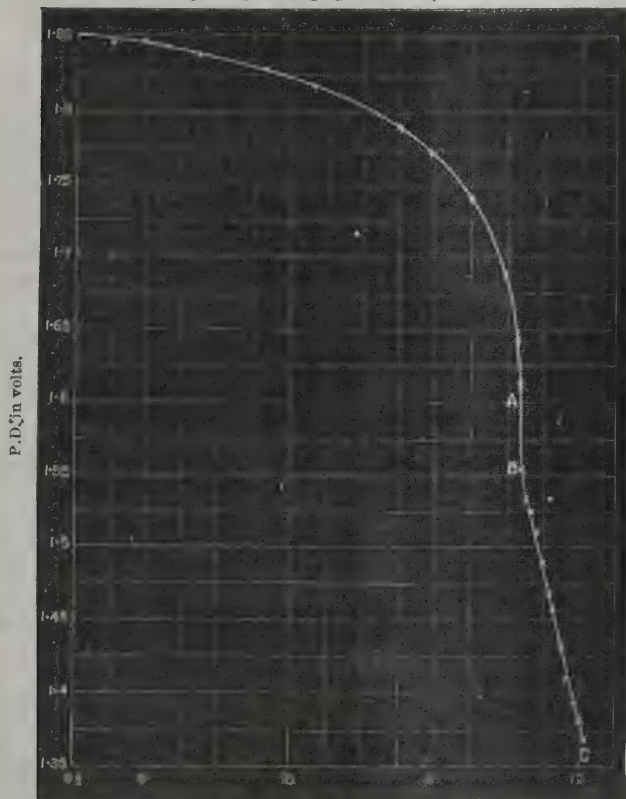

Time in hours from beginning of charge.

FIG. 1.

is far too small to be read very accurately with ordinary hydrometers. But it is known the fall in the E.M.F. of the cells at the end of the discharge is very rapid, so that half an hour more or less in the time of discharge produces a great difference in the value of the

Potential difference per cell, discharging with 10 ampères. End of discharge.

Time in hours from beginning of discharge.

FIG. 2.

E.M.F.; hence it follows that, if a specific gravity test were alone employed with our cells as a criterion of charge and discharge, it would be necessary to read the specific gravity accurately to less than 0.001 at the end of the discharge. The

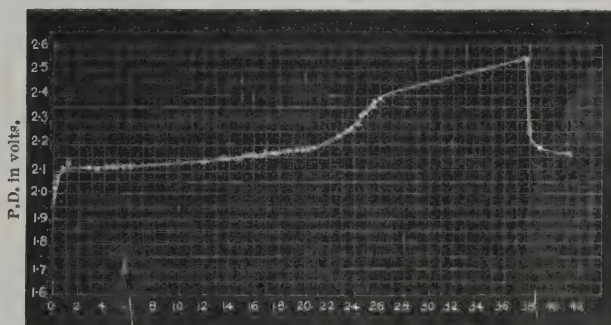

amount of gassing is also far too rough a test, and cannot be employed at all in the discharge, hence we were led to resort to the variation in the P.D.

A number of experiments were now made on two of the cells, in order that the exact shape of the curves of P.D. at the end of the charge and discharge might be ascertained. The curve shown in fig. 1 is the end of the P.D. curve for one cell on charging with 9 ampères for 14 hours; from which we see that the rate of variation of the P.D. with time is greatest when the P.D. is about 2.36 volts, indicated by the point, A. In fig. 2 is shown the curve of P.D. during the last 3½ hours of discharge with 10 ampères, the discharge being continued for 12 hours. In this particular experiment the discharge was allowed to continue until the P.D. fell to 1.365 volts, indicated by the point, c, which is far lower than we have dared on any other occasion to allow the P.D. to fall. At about 1.8 volts the P.D. curve begins to fall pretty rapidly, and the slope of the curve, or the rate of diminution of the P.D. with time, goes on increasing until the P.D. has fallen to 1.6 volts, indicated by the point, A, on the curve in fig. 2. Here

$\frac{dv}{dt}$  per cell has reached a value 1.4, v being measured in volts and t in hours. Below this the curve has a shape that has not hitherto been noticed, for when the P.D. per cell has reached 1.556 volts, indicated by the point, B, the curve suddenly alters its shape, becoming the straight line, B, c, with a less inclination to the axis of time,  $\frac{dv}{dt}$  being for this line only 0.44.

Potential difference per cell, charging with 4.52 ampères.

Charging circuit broken.

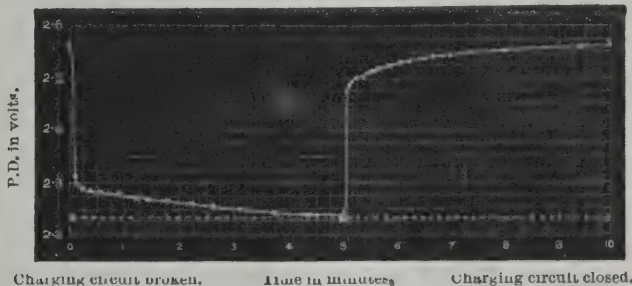

Time in hours from beginning of charge.

FIG. 3.]

Just as we have in the curve in fig. 2 continued the discharge much below the usual limit, so we examined what would take place if the charging was also prolonged much beyond the usual limit. Curve 3 shows the rise of the P.D. when the charging at 4.52 ampères was continued for 37½ hours, 25½ hours being sufficient to fully charge the cells with this constant current of 4.52 ampères—that is, to charge them until the P.D. per cell was 2.4 volts. It will be observed that whereas the volts rise from 2.25 to 2.38 between 23.1 and 25.5 hours—that is, 0.13 volt per cell in 2.4 hours—the rise in the following 12.3 hours is only from 2.38 to 2.55 volts: this is only 0.17 volt. The continuation of the curve shows the drop of P.D. on breaking the charging circuit; there is an instantaneous fall of 0.28 volt per cell, and a further fall of 0.1 volt in the E.M.F. in two hours.

Potential difference per cell, charging with 9 ampères.

Charging circuit broken.

Time in minutes

Charging circuit closed.

FIG. 4.

The curve on fig. 4 shows on a larger scale this drop on breaking the charging circuit when the cells are very well charged, leaving it broken for five minutes, and then closing it again; the charging current in this experiment being 9 ampères. There is, we see, a nearly instantaneous drop of the terminal P.D. per cell from 2.56 to 2.31, then a steady fall in the E.M.F. from 2.31 to 2.24 volts in five minutes. On reclosing the charging circuit at this moment, there is an instantaneous rise of the P.D. to 2.48 volts, and then a slow rise to 2.56 volts in five minutes; so that after reclosing the charging circuit it took, in this experiment, the same time for the P.D. to recover the value it had just before breaking as the time during which the circuit remained broken.

Experiments were also made on the time rise of the E.M.F. on stopping the discharge. Later on, however, the time rise of the E.M.F. on breaking the discharge circuit, as well as the time fall of the E.M.F. on breaking the charging circuit, for various currents, was measured in a far more sensitive way than in the early

part of this investigation; this subject will, therefore, be left until farther on in this paper.

On starting a discharge the P.D. generally falls slightly to the value that is maintained fairly constantly during a long portion of a discharge. After a prolonged rest, however, we have found that the P.D., on the contrary, shows a *decided rise* at the commencement of a discharge, and that it is not until the third discharge takes place that the curve resumes its normal character with the slight drop in the value of the P.D. at the commencement of the discharge.

## II.—EFFICIENCY.

In the earlier of the experiments made by us on the efficiency two distinct groups, each of 10 cells, were employed. The current passing through the two sets of cells also passed through two platinoid strips, and the P.D. at the terminals of each of these platinoid strips was measured by a suitable low resistance galvanometer, whose indications, therefore, measured the respective currents passing through the two sets of cells. The P.D. at the terminals of either group of cells was measured by means of a high resistance D'Arsonval galvanometer, which by means of a switch could be connected with the terminals of either of the two groups. The high resistance and one of the low resistance instruments have been absolutely calibrated very frequently during the past few years, by means of the silver voltameter, known resistances, and Latimer Clark standard cells. A special calibration was also taken of these instruments, both just before these experiments were commenced, and at their conclusion.

Group No. I. of 10 cells was first charged with 9.05 ampères and discharged with 9.933 ampères, there being four discharges alternated with four charges, without intermission, from January 8th to January 12th, 1889, both days inclusive. One of the observers was always present (day and night) to keep the current constant by hand regulation, to take frequent readings of the P.D. at the terminals of the set of 10 cells, to stop the charging when the P.D. per cell reached 2.4 volts and immediately start the discharging, as well as to stop the discharging when the P.D. per cell reached 1.6 volts, and instantly start the charging again, so that the cells were never left discharged.

We used the limits 2.4 and 1.6 volts per cell as the criterions for stopping respectively the charge and discharge since, as already seen, the slope of the charge and of the discharge curves are greatest for about these values of the P.D.

Next, Group No. I. was charged with 4.519 ampères and discharged with 9.933 ampères, twice, without intermission, from January 14th to January 19th, inclusive; the P.D. limit for charge being 2.4 volts, and for discharge 1.5.

And while the two sets of tests were being made with Group I., Group II. was first charged with 9.104 ampères, and discharged with 4.858 twice, without intermission, from January 9th to January 12th. And lastly, Group II. was charged with 4.519 ampères, and discharged with 4.858, without intermission, from January 14th to January 19th, both days inclusive.

Shortly, then, the tests were—

	Charge.	Discharge.
Group I. ... ..	{ 9 4½	... 10 ampères. 10 "
Group II.... ..	{ 9 4½	... 5 5 "

The coarse adjustment of the resistance for keeping the current constant was effected by means of resistance coils made of bare German silver wire suitable for standing large currents; the fine adjustment was performed by means of horizontal mercury troughs, through which the current passed, the lengths of the mercury in the wooden troughs through which the current passed being varied by copper bridge-pieces. This mercury trough arrangement forms an extremely convenient resistance for delicate adjustment by hand. To keep the current as constant as possible, a dynamo was not used to charge the accumulators under test, but they were charged instead from other accumulators of much greater storage capacity.

The general expressions for the ampère hours and watt hours given out by an accumulator are, of course,

$$\int_0^{t_1} A_1 dt, \text{ and } \int_0^{t_1} A_1 v_1 dt,$$

where  $A_1$  and  $v_1$  are the current in ampères passing through the accumulator, and the P.D. at its terminals at any moment, and  $t_1$  is the time in hours during which the discharge lasts. Consequently, if  $A_2$ ,  $v_2$ , and  $t_2$  have similar meanings for the charge, the complete expressions for the quantity and energy efficiency are, respectively,

$$\int_0^{t_1} A_1 dt + \int_0^{t_2} A_2 dt,$$

and

$$\int_0^{t_1} A_1 v_1 dt + \int_0^{t_2} A_2 v_2 dt.$$

In our experiments  $A_1$  has a constant value during the discharge, and  $A_2$  a constant value during the charge, so that the expressions for the quantity and energy efficiency reduce themselves to

$$\frac{A_1 t_1}{A_2 t_2},$$

which is very easy to calculate,

$$\text{and } A_1 \int_0^{t_1} v_1 dt + A_2 \int_0^{t_2} v_2 dt.$$

To obtain  $\int_0^{t_1} v_1 dt$  a time curve of the values of  $v_1$  is drawn

and integrated; similarly, to obtain  $\int_0^{t_2} v_2 dt$  a time curve is drawn

for  $v_2$  and integrated; then, multiplying the first integral by the steady value of the discharge current  $A_1$ , and the second integral by the steady value of the charge current  $A_2$ , we have, respectively, the watt-hours given out in the discharge and the watt-hours put into the accumulators in the charge.

After drawing a series of time curves for the P.D. in the various experiments already referred to, and integrating them with an Amster's integrator, we obtained the following results for the successive charges and discharges:—

### Group of 10 Cells—No. I.

Discharge at 9.933 ampères.		Charge at 9.05 ampères.		Percentage.	
Ampère hours.	Watt hours.	Ampère hours.	Watt hours.	Quantity efficiency.	Energy efficiency.
119	2,280	114	2,435	105	94
105	2,045	102	2,220	103	92
101	1,970	101	2,220	100	87
104	2,020	104	2,270	100	89
Discharge at 9.933 ampères.		Charge at 4.519 ampères.			
112.5	2,170	115	2,485	98	87
113	2,190	115	2,485	98	88

### Group of 10 Cells—No. II.

Discharge at 4.858 ampères.		Charge at 9.104 ampères.		Percentage.	
Ampère hours.	Watt hours.	Ampère hours.	Watt hours.	Quantity efficiency.	Energy efficiency.
154.5	3,005	138.5	2,910	111.5	103
141.5	2,770	129.7	2,820	109	98
Discharge at 4.858 ampères.		Charge at 4.519 ampères.			
143	2,785	141	3,075	102	90.5

Now not only are quantity efficiencies of 105, 103, 111, 109, &c., per cent. impossible, but energy efficiencies of 94, 92 per cent. are also too high, when accumulators are being charged and discharged at the maximum rate allowed by the manufacturers. Further, it is noticeable that for each set of tests both the quantity and energy efficiencies diminish on the whole as the tests proceed. These cells, like the other cells in the Central Institution laboratories, have been charged at regular times; and as the number of ampère hours taken out of them for ordinary laboratory work varies very much, the intervals between the periodic chargings are so arranged that on the whole the cells are charged up much more than they are discharged.

Hence at the commencement of these tests the cells had a large store of energy in them on which to draw in the discharges, the results of which are given in the preceding table. From this we learn this very important fact—that if accumulators be thoroughly well charged up before being tested, then five days' continuous charging and discharging alternately with even the maximum currents allowed by the manufacturers fails to give the normal quantity, or energy, efficiency.

It will be noticed that both the ampère hours and the watt hours are increased by diminishing the current employed. This is partly due to the fact that if a fixed P.D. limit per cell be employed either in discharging or charging, the cell is discharged until the E.M.F. is slightly lower, and charged until the E.M.F. is slightly higher for a small current than for a larger one.

## III.—AUTOMATIC CURRENT REGULATOR.

We think it possible that a neglect of the power that accumulators possess of drawing on a store of energy put into them in former chargings may have led experimenters to conclude that the normal efficiency of certain types of accumulators was greater than was really the case. To ascertain the *working efficiency* of the accumulators we were testing, it was clear that they would have to be charged and discharged alternately with a definite charging and a definite discharging current continuously for a much longer period than five days. And as this would be a very laborious operation if the current had to be kept constant day and night during this period by hand regulation, we proceeded to construct the automatic current regulating device shown in fig. 5:

A is a set of five accumulators under test, where B is a totally independent set of four used to provide the power for working the current regulator. C is a platinum strip of sufficiently large cross section and surface that no appreciable change of resistance can take place by the largest current—10 amperes—that flows through it in these experiments. D is a permanent magnet motor, the rotation of which in either direction turns the brass roller, E, F, very slowly in one direction or the other, the pinion and toothed wheel of the motor, combined with the small grooved pulley on the toothed wheel shaft and the much larger grooved pulley on the roller, causing the angular motion of the roller to be about  $\frac{1}{500}$ th of the angular velocity of the armature of the permanent magnet motor. The brass roller, E, F, is electrically divided into two halves by the ebonite disc, G, and little amalgamated discs at the ends of this roller turn with but little friction in mercury cups, H, I. Round each half of the roller are wound four bare platinum wires of No. 26 gauge, and each about  $4\frac{1}{2}$  feet long. Their lower ends are soldered to the brass roller, and their upper ends to the brass bar, J, K, small spiral springs (not shown in the figure) being introduced to keep the wires taut. The rod, J, K, is held up by a cord which passes over two pulleys, and to the end of which is attached the weight, L. An electric current entering at H follows the path, H, E, J, K, F, I, the path being longer or shorter depending on the amount of the platinum wires wound on the two halves of the brass roller. M is a solenoid, being, in fact, the coil of an A. and P. ammeter. N is the axis of which a rod, P, Q, was very delicately poised by its being supported by four very fine wires of No. 40 gauge, and each about one foot long. Two of the wires, R, on a plane at right angles to the path, joined together where they

When the cells, A, under test were being charged by means of a set of accumulators not shown on the figure, but attached to the leads, T and U, three copper bridge-pieces were put in to connect the mercury cups, 4 to 5, 2 to 6, and 1 to 3, respectively; whereas when the test cells were being discharged two copper bridge pieces connected the mercury cups, 2 to 3 and 5 to 6. The current passed, of course, one way through the cells, A, in charging, and the other way in discharging; but in both cases a positive current flowed, as indicated by the arrows, through the thick lead, V, the platinised strip, C, through H, E, J, K, F, I, through the thick lead, W, the thick lead, Y, the solenoid, M, and the thick lead, Z. As already explained, if the currents through this circuit exceeded in the very least 9 amperes, the core, P, Q, was sucked into the solenoid, M, until P made contact with R; whereas if the current fell in the least below 9 amperes, P, Q was pulled back by the spring, P, P', until P made contact with S. In the former case a small auxiliary current from the accumulators, B, follows the course, a, b, c, d, through the spirals, e—several in number, so as to carry the current, but made of extremely fine wire, so as to oppose practically no resistance to the free motion of P, Q—then from P to R, through f, the electro-magnet, g, and through h, back to the other pole of the battery, B. If, instead, P be in contact with S, then the current from the auxiliary accumulators, B, passes from P to S through the relay electro-magnet, i, instead of through the relay electro-magnet, g. In the former case the spring tongue, k, is attracted so as to make contact with M (M being in reality a mercury cup into which dipped a platinum point with which k was tipped), and in the latter case the spring tongue, l, is attracted so as to make contact with m. If k makes

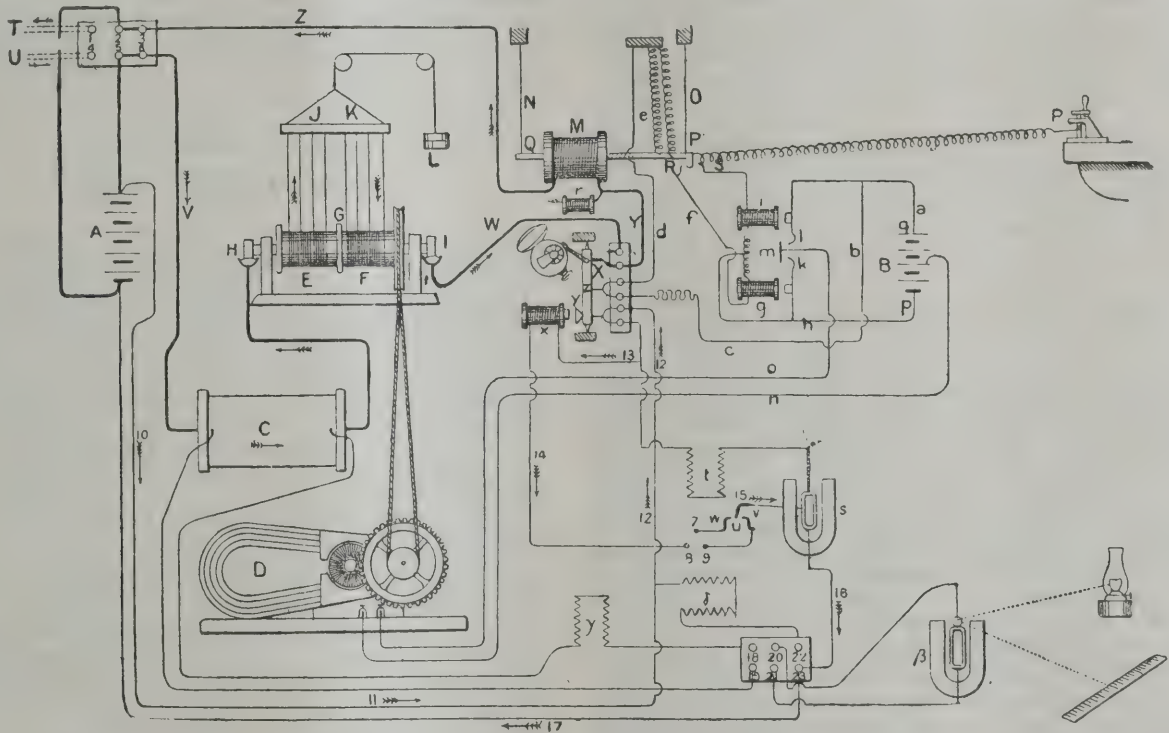

FIG. 5.—AUTOMATIC CURRENT REGULATOR, AND AUTOMATIC INTERRUPTOR FOR BREAKING THE CHARGING AND DISCHARGING CIRCUITS.

were connected with the rod at Q, but spread out at the top, and similarly O consisted of two wires. Thus, while the rod, P, Q, had great freedom of motion along its axis, it could not wobble sideways. This rod consisted of two pieces of brass at its ends, but the middle shaded portion was the well-annealed soft iron tubular core of the ammeter. A current passing round the coil, M, sucked in the core more or less against the pull of the antagonistic spiral spring, P, P'. This spring was made of platinum wire of No. 26 gauge, wound round a  $\frac{3}{4}$ -inch mandril, and when pulled out in position it had about 30 turns to the foot, and was over 4 feet in length. One end of the spring was attached to the rod at R, while the other, P', was fastened to a fine thread, which could be wound up more or less round a small roller and the tension of the spring very delicately adjusted.

At first the elasticity of this spring was not perfectly constant, but after about one month's use the pull it exerted when stretched to a given length became wonderfully definite, and the core, P, Q, could be adjusted so that for a current of exactly 9 amperes flowing round the solenoid, M, the projection at R remained midway between the contacts, R and S, without touching either. But on the current flowing round the solenoid, M, becoming very slightly greater, or very slightly less, than 9 amperes, the platinised projection of the rod at R made contact with either the platinised piece, R or S. The permanency that the spring eventually attained was so great that even when the apparatus had not been in use for two or three weeks, one had only to close the circuits to start the regulator, and no fresh adjustment whatever of this spring was necessary to ensure that the current would be kept absolutely constant at 9 amperes. This spring has, however, now gone the way of most bare fine platinoid wire, of breaking up into pieces.

contact with m, a positive current commencing from the middle of the accumulators, B, follows the path, n, the motor, through o, m, k, and back to the end of the accumulators, p; whereas if l makes contact with m, a positive current follows the path q, a, l, m, o, the motor, through n, and back to the middle of the cells, B.

Accordingly, then, as P makes contact with R or with S, a current is sent one way or the other through the armature of the permanent magnet, D, and the roller, E, F, is turned around one way or the other so as to unwind, or wind up, more of the wire and automatically alter the resistance in the circuit. Although the whole apparatus was home-made, and looked very rough, it was able to automatically keep the current constant to 1 part in 600 for days at a time.

As the charge was effected with 9 amperes, and the discharge with 10, a shunt, r, exactly nine times the resistance of M, was connected across M during the discharge, and as the automatic regulator kept the current through M constant at 9 amperes, it kept the current through the circuit constant at 10 when the shunt, r, was attached to M.

The necessity of using the relay electro-magnets, g and i, arose from the fact that the only suitable permanent magnet motor which was at our disposal was a laboratory hand magneto Gramme machine, which required a current of about one ampere to work it, and to obtain great sensibility, the contacts between P and R, or P and S, had to be too slight to carry such a current.

It was very interesting to watch the regulator, since the armature of the motor was almost always in motion, now making half a turn one way, now one turn the other. It may be mentioned that one turn of the motor armature shortened or lengthened each

of the platinoid wires by about the 62nd of an inch—that is, by less than the  $\frac{1}{1000}$ th of its whole length.

At first all sorts of plans were tried for keeping clean the surface of the mercury in the mercury cup, *m*; but alcohol floated on the mercury failed because it dried up, water was electrolysed, oil was carbonised, and a long conducting point adhered to each of the platinum points, *l* and *k*, and the auxiliary accumulators, *B*, were short-circuited. In despair, we left the surface of the mercury completely exposed to the air, and were surprised to find that that answered perfectly; a thickish layer of mercury and mercurous oxide formed on the top, but the platinum wires easily forced their way through, and always made good contact.

To avoid, however, all risk of accidents, cut-outs were introduced into various parts of the circuit; and to prevent the motor overwinding the platinoid resistance wires on the roller, *E*, *F*, and breaking them, should the current in the main circuit accidentally become much too small, as well as to prevent the motor unwinding the wires too far off the roller should the current become much too large, safety keys (not shown in the figure) were provided. If the red, *J*, *K*, were drawn down dangerously low, or allowed to go up too far, it touched one or other of the safety keys and broke the electrical circuits.

#### IV.—AUTOMATIC INTERRUPTOR FOR BREAKING THE CHARGING AND DISCHARGING CIRCUITS.

As it was extremely important that both the charging and discharging circuits should be broken at the exact moment when the P.D. in its rapid variation passed through certain specific values, and as in a long course of experiments, lasting for several months, it was quite possible that occasionally no one of the observers would be present at the exact moment, we arranged an interruptor to break the circuit automatically when the P.D. in charging reached 2.4 volts per cell, or 1.6 volts per cell in discharging. The automatic interruptor was arranged thus:—*s* is a D'Arsonval galvanometer, the coil of which, wound with platinoid wire of 154 ohms resistance, is joined in series with a resistance box, *t*, as a shunt to the accumulators, *A*, under test. Electric connection was made to the bottom of the coil by means of a fine spiral spring, too thin to introduce any controlling moment, while above the coil was suspended by a phosphor bronze strip  $\frac{1}{1000}$ th inch thick,  $\frac{1}{1000}$ ths broad, and  $1\frac{1}{2}$  inches long. This strip has seven twists put into it by means of a head moving in a tight collar, the coil being prevented from turning by a pointer, *u*, attached to the framework of the coil coming into contact with the stop, *v*. The thin phosphor bronze strip being very thin, it had very little torsional rigidity, and being set up as described, this instrument acted as a "set-up voltmeter"—a type of instrument proposed years ago by Prof. Perry and one of the authors of the paper for measuring with great accuracy a very small change in a P.D. With a definite adjustment of the resistance in the box, *t*, the platinum-tipped pointer, *u*, remains in contact with the stop, *v*, for all P.D.'s between the terminals of the accumulators, *A*, less than 2.4 volts per cell. When the P.D. reaches this value, the pointer at once leaves the stop, *v*, moves over through an appreciable distance, and makes contact with the platinum-tipped stop, *w*. With another definite adjustment of the resistance in the box, *t*, the pointer, *u*, remains in contact with *w* for all P.D.'s between the terminals of the accumulators, *A*, greater than 1.6 volts per cell, but the moment this value is reached the pointer moves away from *w* and makes contact with the platinum-tipped contact stop, *v*.

When charging, a copper bridge piece connects the mercury cups, 7 and 8, and when on the P.D. at the terminals of the accumulators, *A*, reaching 2.4 volts per cell, the pointer, *u*, passes over and makes contact with *w*, an instantaneous small current is sent by the accumulators, *A*, through the electro-magnet, *x*, which, attracting the armature, *y*, downwards, tilts the spindle, *z*, and thereby lifts *x* and the other two contact forks out of the three sets of mercury cups, thus breaking all the circuits. The tilting of the spindle, *z*, also brings a camel's-hair brush into contact with the balance of a watch, and stops it at the moment the charging is completed.\*

In discharging the cells, *A*, mercury cup 7 is connected to 9 instead of to 8. During the discharge the pointer, *u*, rests against *w*, and on the terminal P.D. of the cells falling to 1.6 volts per cell, the pointer moves over, comes into contact with *v*, and an instantaneous current passes round the electro-magnet, breaks all the circuits, and stops the watch. The course of this instantaneous current at the end of the charge and discharge is indicated by the arrows numbered consecutively 10, 11, 12, 13, 14, 15, 16, and 17.

To prevent any sluggishness in the action of this interruptor from a possible sticking of the pointer, *u*, against the contact stops, *v* or *w*, the pedestal supporting the set-up galvanometer, *s*, was kept in a constant state of slight vibration by the going of an American clock works that were placed on this pedestal.

#### V.—AMMETER AND VOLTMETER.

There remain only to be described the ammeter by means of which the current passing through the accumulators could be measured from time to time in order to see whether the automatic

regulator was doing its duty, and the voltmeter for frequently measuring the P.D. at the terminals of the accumulators, *A*, under test. As the current had only to be very occasionally measured, one D'Arsonval galvanometer, *B*, was employed for both purposes. Its coil was wound with platinoid wire of 52 ohms resistance, and suspended in the way that has been already described,\* which enables the deflection from one end of the scale to the other to be absolutely proportional to the current. The top suspension was a phosphor bronze strip  $\frac{1}{1000}$ th inch thick,  $\frac{1}{1000}$ ths wide, and about  $1\frac{1}{2}$  inches long; while electric contact was maintained with the bottom of the coil by means of an extremely fine *A*. and *P*. spring, offering no appreciable torsional rigidity. The permanent magnets employed belonged to an old magneto machine, and into the cylindrical space between their poles, in which the Siemens armature formerly turned, was put a coil made of the right shape to suit the curved ends of the magnets without it being necessary to employ any soft iron pole pieces. Experiment showed that the deflection right across a scale 2 feet 9 inches long, the zero for no current being at one extreme end, was rigorously proportional to the current—a result which, as has been already pointed out, is far from being obtained with D'Arsonval galvanometers as usually constructed.

When it was desired to measure the current passing through the accumulators, *A*, a rocking switch was turned so as to connect mercury cup 18 to 20 and 19 to 21; whereas when it was the P.D. at the terminals of the accumulators that was to be measured, the rocking switch was turned so as to connect mercury cup 20 to 23, and 21 to 22. In the former case, with a resistance of 264 ohms on the resistance box, *γ*, a current of 10 amperes passing through the cells and platinoid strip, *c*, produced a deflection of 500 scale divisions, or 50 divisions per ampere; while, with a resistance of 71,570 ohms in the resistance box, *δ*, a P.D. of 10 volts at the terminals of the five accumulators, *A*, under test produced the same deflection; so that 50 divisions corresponded then with 1 volt.

(To be continued.)

#### NEW PATENTS—1890.

10125. "Improvements in electric cut-outs or apparatus for controlling the flow of currents of electrical energy." J. L. KIMBALL and H. C. WIRT. Dated July 1. (Complete.)

10134. "Improvements in covered or insulated electric cables or conductors, and a compound therefor." J. Y. JOHNSON. (Communicated by J. H. Cheever, United States.) Dated July 1. (Complete.)

10137. "Obtaining motive power by a method and means, or apparatus in connection with any mechanical or electrical motor, or combination of both." P. H. WILLIAMS. Dated July 1.

10179. "Improvements in telephone call devices." H. J. HADDAN. (Communicated by F. R. Spalding, United States.) Dated July 1. (Complete.)

10181. "Improvements in secondary batteries." T. M. FOOTE. Dated July 1. (Complete.)

10183. "Improvements in electrical cut-outs, and fixtures connected therewith." H. H. LAKE. (Communicated by S. Bergmann, United States.) Dated July 1.

10187. "Improvements in or appertaining to self-exciting electric generators." W. P. THOMPSON. (Communicated by W. Stanley, Jun., and O. B. Shallenberger, United States.) Dated July 1.

10211. "Improvements in electric primary batteries." V. FABRIS. Dated July 2.

10229. "Improved means for decomposing sewage water by oxidising zinc by electric current." A. GREEN. Dated July 2.

10252. "Improvements in electric railways." J. P. BAYLY. (Communicated by T. A. Evans, United States.) Dated July 2.

10271. "An improvement relating to medico-electric batteries." N. MITCHELL. Dated July 2.

10276. "Improvements in electric search lights and in mechanism for feeding the carbons." H. J. ALLISON. (Communicated by B. B. Ward, United States.) Dated July 3.

10305. "A combined electrical comb-curler and curling tongs for hair." W. H. FASSETT. (Communicated by R. Scott, United States.) Dated July 3.

10309. "An improvement in adjusting electric light suspenders." A. LUCAS and E. SUNDBORG. Dated July 3.

10316. "Improvements in joints for armoured electric conductors." J. D. F. ANDREWS. Dated July 3.

10342. "Cleaning knives. Intended to be called 'Coomer's electric knife cleaner.'" G. M. COOMER. Dated July 4.

10359. "Improvements in connection with the electric lighting of ships." T. W. WATSON and A. H. WATSON. Dated July 4.

10406. "Improvements in electrical measuring instruments." J. PERRY. Dated July 5.

10421. "An improved method or means for the prevention of accidents from the overheating of electrical wires." J. BRADFORD. Dated July 5.

10445. "An improved electric prod-pole." J. P. BAYLY. (Communicated by J. Burton, E. Roach, R. Mac Nair, W. P. MacNair, and C. Lanning, United States.) Dated July 5.

\* As it was undesirable to risk an expensive watch, we purchased one of the watches that could be then obtained in St. Paul Churchyard for 3s. 5d. This watch was very substantial, had a very strong hair spring which could not be easily damaged, and was an excellent time-keeper—far superior to many watches of a far more expensive character.

\* See paper on "Galvanometers," *Phil. Mag.*, July, 1890.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1889

5066. "Improvements in sockets or holders for incandescent electric lamps." P. A. NEWTON. (Communicated from abroad by A. Swan, of America.) Dated March 23. 8d. The holder is composed of insulating material of a plastic nature, such as papier maché, moulded preferably to the form of a truncated cone. The base of the cone is recessed to receive the base of the lamp, through which pass the insulated wires leading from the carbon filament to insulated contact plates or rings on the surface thereof. The holder is pierced with ducts or passages for the leading wires from the electric main circuit, and recesses are provided in connection with these ducts containing contact plates or terminals. 19 claims.

5623. "Improvements in and connected with telegraphic apparatus for transmitting orders or other communications," G. A. CALVERT. Dated April 2. 11d. Consists in applying to the receiving instrument of the telegraphic apparatus a device to cause a bell or other sounder to sound or continue sounding in the event of the person receiving an order or communication making a mistake in the direction in which he moves a lever or other part when obeying the order or acting in consequence of the communication. 5 claims.

6728. "Improvements in the method of and means for the distribution of electrical energy by alternating currents." GISEBERT KAPP. Dated April 20. 8d. Claims:—1. In a regulating transformer, subdividing the primary or thin wire coil into sections and connecting each of the sections with a multiple contact switch, substantially as and for the purpose hereinbefore described and as indicated by the drawings. 2. A regulating transformer in which the induction through the secondary or thick wire coil is varied by altering the relative positions of the two coils and their cores, and of a third or intermediate core, substantially as described and as illustrated by the accompanying drawings. 3. A regulating transformer in which the induction through the secondary or thick wire coil is varied by the motion of a movable magnetic bye-pass, substantially as described and as illustrated by the drawings.

7600. "Improvements in electric indicators." B. C. C. CANT. Dated May 7. 6d. Consists of a new form of armature which bears on its outer side a small lug and a new form of flag, having at the apex of a circle a small curved lug which engages and is supported by the lug on the armature when by a quick motion of the electric current the lug is disengaged and the flag falls, indicating in which room or place the circuit has been made. There are various devices for better adjusting the correspondence of parts. 1 claim.

7719. "Improvements in electric or galvanic elements or cells." Dr. P. SCHOOP. Dated May 8. 6d. Claims:—1. An electric or galvanic element or cell having an acid or saline exciting body or electrolyte in a solidified or thick gelatinous state produced by adding water glass (i.e., silicate of potash or of soda) to a solution of an acid or of a saline substance, substantially as described. 2. An electric or galvanic element or cell having a solidified or thick gelatinous alkaline exciting body or electrolyte produced by adding to an alkaline liquid a solution of a salt of iron, such as sulphate of iron, either alone or mixed with hydrate of soda or water glass, substantially as described. 3. The production of an exciting body or electrolyte, such as hereinbefore referred to, by the conversion of an acid or saline solution into a solidified or thick gelatinous mass by means of a solution of water glass, substantially in the manner described for the purpose specified. 4. The production of an exciting body or electrolyte, such as hereinbefore referred to by the conversion of an alkaline solution into a solidified or thick gelatinous mass by means of a solution of a salt of iron, such as sulphate of iron, with or without admixture therewith of hydrate of soda or of water glass, substantially as described. 5. In the production of an electric element or cell of the kind referred to, the use of fibrous substance, such as asbestos fibre, in the manner and for the purpose set forth.

## CORRESPONDENCE.

### Secondary Battery Manipulation.

I send the following experience in case it may be of any interest.

Last year I filled in the spaces between the plates of my accumulators with plaster of Paris and sawdust in a dry state, intimately mixed, and then put in the usual dilute acid to which a little carbonate of soda had been added. I used these cells in conjunction with a dynamo driven by a turbine for lighting purposes; they were last charged early in November of last year, and on returning here late in June, I found that they burnt the lamps at their usual brightness, and that the E.M.F. of each cell was just under 2 volts. I also found that

the cells had lost very little of the liquid through evaporation.

W. J. S. Barber-Starkey.

Knockshandoch, Glen-Isla, Alyth, N.B.  
July 9th, 1890.

### Lubricating Oils.

If, from the report in a contemporary journal of a recent case of litigation, arising out of some experiments with a particular kind of lubricating compound called *valdoline*, we may draw any conclusion from the evidence of the witnesses, especially one describing himself as a mechanical engineer, we shall probably be led to believe that this particular compound is an unfailing lubricant for such work as is included in electric lighting, or that, as stated in the evidence of the plaintiff company, it is a complete failure for electric machinery. But this brings the subject of lubricants before us for more general thought, and compels us to enquire into the particular advantages, special and general, claimed for innumerable compounds possessing ordinary and oftener extraordinary names, and, as a rule, very ordinary lubricating properties. For what particular object there should be such a desire on the part of oil sellers and inventors, as they often term themselves, to make their lubricants as complex as possible by mixing really good mineral oils with all manner of rubbish in the shape of acid fats and oils of animal and vegetable origin, is not easily explained. It can be supposed that every lubricant "inventor" has his own particular fancy of what constitutes a good lubricant, and maybe has the idea that by making the lubricant complex in character, and by giving it an attractive or, more generally, repulsive name, it will command a ready and profitable sale under "good pushing men."

If we follow the experience of those works where engines and machinery are running continuously from year to year, we obtain some reliable data as to the lubricants which give the greatest satisfaction, and it behoves those electrical engineers who have the charge of heavy and continuous-running machinery to follow, as far as may be practicable, the experience acquired by others under similar conditions. Now, what is the experience of engineers regarding lubricants? I have gone to considerable trouble to ascertain opinions of reliable men in many mills and factories, and who are not to be "bought" or bribed by the cleverest of oil touters, and they are unanimous in recommending pure hydro-carbon, or, as generally termed, mineral oils of various specific gravities, in proportion to the work being done. There are such things in the market as pure mineral lubricating oils, and can, I believe, be easily obtained at a reasonable price. One thing I would point out is that the purest oil put in a dirty tank or cask will most assuredly become gritty by the actual suspension of fine grit, generally fine silica, especially if the oil be very dense; and this is often the cause of sudden screeching bearings. The grit can be separated by washing the oil in water and allowing to settle; but it is best to avoid the cause by watching the barrels.

Probably the tricks of oil touters exceed any other calling in general engineering. It was actually admitted to me by an engineer in charge of an electric plant at an exhibition in London that the oil he used, and that most abundantly, was that which was "watered" the most! But jobbery of this kind should be completely quashed; not in lubricants only, but in bigger fields where it is known to exist, in the electrical world.

James C. Richardson.

### Telegraph Statistics in Australia.

In your issue of February 14th you publish certain statistics purporting to be the postal and telegraph statistics of the colony of New South Wales. As the figures you give are so entirely erroneous, I am desired by Mr. Cracknell, the Superintendent of Telegraphs, to

forward you the correct figures (attached), with the request that you will kindly correct the errors.

Arthur C. F. Webb.

FOR THE SUPERINTENDENT OF TELEGRAPHS.

Electric Telegraph Department, Sydney,  
June 9th, 1890.

#### TELEGRAPH STATISTICS.

	Corrected figures from official reports.	Figures as given in the ELECTRICAL REVIEW.
No. of stations	485	210
Total mileage of lines open for traffic December 31st, 1889	10,732	5,436½
Total mileage of wires open for traffic December 31st, 1889	22,606	9,921
Total mileage of lines opened during year	143	145½
Total mileage of wires opened during year	488	291
Total mileage of lines dismantled, ditto	102	145½
No. of local and inter-colonial telegrams transmitted	3,415,545	918,454
No. of cables from this colony per International cable...	10,271	...
No. of cables from this colony per New Zealand cable	9,746	...
No. of cables to this colony per International cable...	8,649	...
No. of cables to this colony per New Zealand cable	8,225	...
Revenue of telegraph department...	£186,861	...
Expenditure of telegraph Department alone	£178,931	...
Revenue of telephone department	£13,360	...
No. of subscribers on Sydney and district exchange	1,161	600
(In addition to this exchange there are exchanges at Newcastle, Maitland, Bulli, Wagga, and Albury)		
Total mileage of lines in progress...	293	11½
Total mileage of wires in progress...	400	23½

#### Electric Traction.

However faint Mr. Stove's praise of the Lineff conductor may be, I should like to ask for what reason the demonstration of its capabilities on 25th ult. is not to be regarded as conclusive.

The crucial points with regard to any sectional traction conductor are :

1. Its reliability.
2. Security to the public.
3. Efficiency, under which may be included the proportion of the power consumed by the picking-up apparatus, and so lost for traction purposes, and the underground and surface leakage.
4. Cost of maintenance.

To take these points in the order in which I give them, I will examine whether any difficulties may be expected to occur in a line of three or four miles on my system, that have not already been met with and overcome in laying a length of 75 yards.

1. *Reliability.*—Since the experimental line was laid down, in no instance has the contact with the conductor been lost, except when (the battery circuit on the car being disconnected) the dynamo has been stopped for the purposes of experiment. During the time the car has run a very considerable number of miles, and as the number of moving parts in the conductor is identical for a short or long length of line, it is absolutely immaterial whether the mileage is made up by many short runs or a few long ones.

2. *Security to the Public.*—Here again the fact of there being only one moving piece in the conductor makes a length of 75 yards quite sufficient for demonstration. No additional element of doubt is introduced by increasing the length of line. From the laws of probability it is clear that the chance of any one of  $n$  switches going wrong is greater than that of any particular one doing so ; so that in a line dependent upon separate switches for its action the uncertainty increases with the length. In the case of my conductor, however, there is no such increase, for the simple reason that the car, so to speak, carries its own

switch with it, and this switch having been demonstrated to work satisfactorily over runs aggregating many miles, it is clear that under this heading, as under the former, the length of each individual run is immaterial.

The existence of a subsidiary wave in my hoop iron, in addition to the main one occurring under the moving magnet, has been thoroughly tested for, and it is proved that there is no such subsidiary wave within the limits of the line I have laid down. That a principal wave  $\frac{1}{4}$ -inch high should induce a secondary wave at a distance of over 75 yards is, as I think you will admit, so very remote a possibility, that it is quite unnecessary to contemplate it.

3. *Efficiency.*—The power absorbed by the picking-up magnet is obviously a constant quantity, and bears a constant ratio (about  $\frac{1}{20}$ th) to the mean power required to drive the small car. It will be less than this on a full sized vehicle. No difference on this head can accordingly occur on a long line.

With regard to underground and surface leakage, a judicious application of Ohm's and Kirchoff's laws will enable satisfactory conclusions for a line three or four miles long to be drawn from observations made on a length of 75 yards.

4. *Cost of Maintenance.*—This, I admit, can only be arrived at by subjecting the conductor to the same conditions as would exist when it was in practical use. But let us see what this means. It would be necessary to run a number of cars for a year or two on a public road before any demonstration took place. If this is not a contradiction in terms, it is so obviously an utterly impracticable expedient, that no apology need be offered for letting events proceed in the reverse order.

With regard to speed, I am at a loss to know how the statement that we had run here at 30 miles per hour originated, as it is clearly an impossibility. My car is geared to run at eight miles per hour, which is the maximum that will be allowed in the streets. Considering that I can start the car, attain this speed, and bring it to rest, all within less than half the length of the track I have laid down, I certainly think my line is long enough to demonstrate the capabilities in the way of speed so far as tramway traffic is concerned.

There are still one or two points to consider in Mr. Baines's letter. In the first place, he seems to think that the same tests are equally applicable to the third rail (by which I suppose he means the parallel), the series, and accumulator systems. Now, sir, is not some distinction necessary? The parallel system being perfectly well established needs no demonstration of its general principles, and a new method of making the connection between the moving car and the conductor can be adequately tested by means of a comparatively short length of line and a single car. On the other hand, the series system certainly requires the use of at least two cars before it can justify its name. Again, an accumulator system cannot be considered as "demonstrated" till the life of the storage cells is determined, and the number of cars and length of track have nothing to do with this.

As to the points on which Mr. Baines wishes to be enlightened, I may say that rain, having no access whatever to the charged main, cannot possibly affect the uncharged surface rails, and that snow, whether wet or dry, will produce equally little result. With regard to clearing away snow, no great difficulty is to be feared. In America, where the falls are much heavier, the electric cars are provided with ploughs, and are able to run when horse cars are absolutely snowed up. In this country it is very rarely that the horse cars have to stop through snow, and the means already adopted for clearing the track in their case can also be applied with equal success to the magnetic rail of my conductor.

Mr. Stove's reply to Mr. Baines was, owing to my absence, sent on to you without being submitted to me, otherwise this detailed answer would have been forwarded last week.

A. Lineff.

## SECONDARY BATTERIES.

IN a speech before the recent meeting of the Old Students Association of the City and Guilds of London Institute, Dr. S. P. Thompson volunteered some remarks to the effect that the series of articles on storage batteries, written by Mr. A. Reckenzaun for the ELECTRICAL REVIEW, were, in his opinion, of the greatest value to electricians, and that he regarded the whole as a standard work on this special subject. These articles, many of our readers will recollect, commenced in 1886, and were completed in 1888; they contained in a concise form nearly all that was then known about secondary batteries; at any rate, as far as their practical working was concerned. Mr. Reckenzaun treated the subject broadly, and he illustrated his observations by an immense array of figures and diagrams, drawn from his own every-day practice. The paper on "The Working Efficiency of Secondary Cells," by Messrs. Ayrton, Lamb, Smith and Woods, which we are reproducing in another place, naturally contains much that has been said and proved by our contributor; it is, nevertheless, of considerable interest, inasmuch as it gives results of new laboratory experiments which not only confirm existing knowledge, but at the same time offer hints for further research in particular directions. Prof. Ayrton and his assistants confined themselves to efficiency tests with a set of 20 E.P.S. cells of the "1888 type," each cell containing seven plates, which are ordinarily charged at the rate of 9 and discharged at 10 ampères; their normal capacity being 130 ampère-hours, and the total weight 59½ lbs. These were charged with a constant current, a task which would have involved an almost intolerable amount of attention, as the experiments ranged over a long period; therefore an apparatus was constructed which regulated the resistances of the circuit automatically, and thus kept the current rate practically the same. This apparatus we illustrated on page 81 of our last issue; it is somewhat complicated, yet ingenious, and it deserves, as far as the main principle goes, the study of those who take an

interest in the automatic regulation of accumulators; a subject which, in practice, is still a long way off finality. Whether a well-made apparatus on the lines indicated in the Edinburgh paper would work without any hitch outside a well-organised laboratory is a question we cannot answer; but, on the face of it, it seems as rational as any we have seen adopted in certain central stations claiming to possess self-regulating devices for charging accumulators. A fine opportunity is now open for some inventive genius to produce an instrument which should give the desired effect with certainty, but without expensive or complicated details.

Concerning efficiency tests, the authors have obtained some remarkable figures; thus it is stated that the ampère-hour efficiencies range between 111 and 98 per cent., and the energy efficiencies between 103 and 88 per cent. From this we are to learn "that if accumulators be thoroughly well charged up before being tested, then five days' continuous charging and discharging alternately, with even the maximum currents allowed by the manufacturers, fails to give the normal quantity, or energy, efficiency." If five days is not sufficient, what should, then, be the correct period, and why should the accumulator first be "thoroughly well charged" without taking proper account of this charge? Cells of the 7L E.P.S. type are supposed to have a capacity of 130 ampère-hours when discharging at the rate of 10 ampères; but the authors, according to table No. I., have only taken 119 ampère-hours out at the first discharge, and then recharged it to 114 ampère-hours. Naturally it would take a good number of discharges to get rid of the large surplus which might originally have been contained in the cells, but of which no account has been taken. Table II. reveals the fact that 154·5 ampère-hours have actually been taken out at the rate of 4·85 ampères, consequently it may have been possible that the battery contained over 50 per cent. more at the commencement of the tests than the experimenters were aware of, and it seems to us inexplicable why Prof. Ayrton allowed such irregularities to be placed on

record, especially as in the division VI. of the paper an account of a more rational method is given on the results obtained with automatic apparatus regulating the work of five accumulators. The experiments on the effect produced on the capacity and efficiency of accumulators by prolonged rests form one of the most interesting parts of this elaborate paper. Five cells, thoroughly insulated to prevent external leakage, were periodically charged, left to stand idle, discharged at long intervals, and the effects carefully noted. "Rest," say the authors, "of an accumulator, although well insulated and fully charged at the commencement, alters the accumulator so that for the first few charges and discharges, after the rest, it is a much less valuable instrument than before. A week's continuous charging and discharging day and night, however, removes this effect to a great extent; the efficiency, however, still remains lower than before the rest." Again, "from all that precedes, it follows that the previous history of an accumulator produces an enormous effect on its efficiency. If, for example, an E.P.S. accumulator be over and over again carried round the cycle of being charged up to 2.4 volts per cell, and discharged down to 1.8 volts per cell, the 'working efficiency' thus obtained may be 97 per cent. for ampère-hours, and 87 per cent. for watt-hours; whereas, if the accumulator has been left for some weeks, then, although it was left charged, the energy efficiency for the first few charges and discharges will be as low as 70 per cent."

Everyone who has had to do with secondary batteries on a practical scale, knows that energy efficiencies of 87 per cent. under normal working conditions are not attainable, and that laboratory tests with a few cells cannot be relied upon as a basis for power calculations. No experienced engineer, not even the most sanguine seller of accumulators, would be justified in allowing more than 77 per cent. efficiency under the most favourable circumstances, and we have often pointed out that the expressions "ampère-hour efficiency, or quantity efficiency," have no meaning whatever, and should be dropped out of the electrician's vocabulary.

The authors carefully avoid advancing any new views on the chemical actions in secondary batteries, and content themselves with quotations from various sources. The sediment that "fell to the bottom of the cells" was analysed; but this is of no importance whatever. If some of the active material had been forcibly removed from plates at various stages of charge and discharge, and analysed immediately, the science of secondary battery reactions would have been enriched to a great extent. This the authors promise to do with the aid of Dr. Robertson, in Dr. Armstrong's laboratory, and the results of these investigations will be looked forward to with anxious interest by a large portion of the electrical fraternity. We have frequently expressed the hope that some competent chemist might take this matter in hand, and, if possible, remove the doubts which still envelope the whole subject.

The experiments on temperature variations, and on the resistance of an accumulator when charging and discharging, are worthy of careful perusal, and, with

the exception of the few deficiencies previously pointed out, the paper of Messrs. Ayrton, Lamb, Smith and Woods must be regarded as vastly superior to many to which we have listened of late at the Institution of Electrical Engineers. The concluding words of the authors, expressing the hope that they may be able to "present a graphical record of the life history of accumulators from their first formation to their death," have no doubt made the minds of the curious more curious, and the hearts of the faithful more faithful. Let us hope that both will be fully satisfied by the time these cells, born in 1888, come, after an eventful career, to their end.

---

### "AN UPRIGHT JUDGE, A LEARNED JUDGE."

---

"I HAVE difficulty in understanding how it is that a considerable number of able and distinguished men should have been persuaded to give their evidence as to the alleged insufficiency of Mr. Varley's description as an anticipation. To a considerable extent, the evidence of the witnesses of the Brush Company is made up of somewhat minute and verbal criticism on the expressions used by Mr. Varley; but, in so far as these gentlemen indicate an opinion as to the insufficiency of the description in its entirety, I think their conclusions are, in part, explained by their having misapprehended the question." These significant words were spoken by Lord McLaren in delivering judgment in the compound winding case, which we publish on another page, and the scientific experts against whom they were directed probably feel that they have escaped the more scathing criticism which their evidence deserved through sheer good nature on the part of the Judge. Misapprehension of the question is a gentlemanly and courteous mode of letting them down lightly; but, in one instance at least, this lack of acquaintance with Varley's specification and previous work led some of the Brush Company's witnesses to fairly overshoot the mark, and attempt to introduce into the case a matter which, on the face of it, was utterly absurd. We refer to the effort to make believe that a separate excitation was necessary with Varley's machine; in other words, that it could not be self-exciting. If the gentlemen who so tenaciously held to this view had only allowed their thoughts to wander back to the time when Varley discovered the reaction principle of the dynamo, they must have known that his inventive genius had been wholly centred on the production of machines which excited themselves; and was it likely that, with the knowledge and experience of after years, he would deviate from the principle on which he constructed his now historical machine?

This feature we have always considered to be one of the lamest points in the whole of the Brush evidence, and its introduction, with nothing in Varley's specification or drawings to suggest such an idea, seems to savour of something beyond mere misapprehension.

However, the whole judgment is so terse, forcible, and so completely in Varley's favour, that any attempt

on our part to bring out particular points would be useless, and we can only hope that with this decision we have heard the last of compound winding in its legal aspect. The attempt to create a monopoly seems to have been a stroke of the "venture nothing, nothing win," policy of the boldest kind, and was doubtless deliberately made with the full conviction that the electrical trade would submit to demands which have twice been clearly proved to be devoid of any legitimate foundation, rather than risk the glorious uncertainty of an appeal to the law. Luckily, however, Messrs. King, Brown & Co. refused to admit claims which they believed to be baseless, and, with a determination and pertinacity worthy of the Scotch race, they have succeeded in twice carrying their case. We are not aware at what determination the Brush directors have arrived, or what complexion of the matter they will present to their shareholders; but it seems too ridiculous to suppose that they will proceed to still further extremities, although the question may be reopened and obstinately prolonged till the expiration of Brush's patent.

Whatever the future may have in store, it must be admitted that great praise is due to the Edinburgh firm for their energy and perseverance in the face of obstacles which would have simply appalled many English manufacturers; and, as they have been put to great expense for the benefit of their fellow traders, it is scarcely credible that they will be allowed to go unrewarded, and we feel that an appeal to the electrical manufacturing interests to enable them to meet their heavy costs, should meet with a cordial response. After the previous trial it was hinted that a substantial testimonial to Mr. Varley would have been a graceful acknowledgment of his inventions, the benefits of which not he, but others, are reaping; and this we trust will now be forthcoming, for but rarely do we come across a case so well deserving recognition.

IN an article on this subject our contemporary *Industries* draws attention to the disturbances which may arise in telephone wires from the leakage from electric light circuits. The whole subject is being fought out before Parliamentary Select Committees, and possibly something definite may be decided in the matter. The sensitiveness of the telephone is well known, but somehow or other, in spite of the considerable network of electric light conductors radiating over the housetops, we do not hear of any serious complaints made by the subscribers to the Telephone Company in London. In America, again, where electric light and electric tramway circuits are rapidly spreading, but little is said of their disturbing effects; it is true that in the case of electric tramways alternating currents are not employed, but even so-called continuous currents are not as a rule so perfectly uniform as to be unable to set up an inductive action. The one certain cure is, of course, double-twisted conductors, and although the cure would be equally efficacious if either the electric light mains or the telephone wires were thus twisted, yet it would probably be cheaper to deal in this way with the tele-

phone circuits rather than with the electric light conductors. It might, perhaps, be suggested that the particular telephone circuits most affected should be duplicated and twisted; this would answer the purpose so long as local work only takes place, but if for exchange purposes a twisted circuit has to be connected to a single wire line, the advantage of the double wire at once disappears.

The Chicago *Illustrated Century* devotes an article to seriously advocating the Pennock primary battery

as a source of motive power for tramways. The inventor calculates that a 10 mile track with 15 cars on the overhead wire system costs \$215,000, the storage battery method \$200,000, cable \$885,000, and the Pennock plan only a fifth of the electrical and one-twentieth of the mechanical systems mentioned. Our contemporary gravely states that Mr. Pennock, by his primary batteries, can do away with the necessity of accumulators, dynamos, overhead wires, &c., and yet run the cars at a mere fraction of their usual cost. Moreover, the speed and power attained is claimed to be far greater than with the steam engine, as will shortly be shown by a train to be run between Chicago and New York by the inventor himself. The *Chicago Illustrated Century* is just 100 years behind the times, and Mr. Pennock will have to add another century to his age before that train with primary batteries knocks out steam.

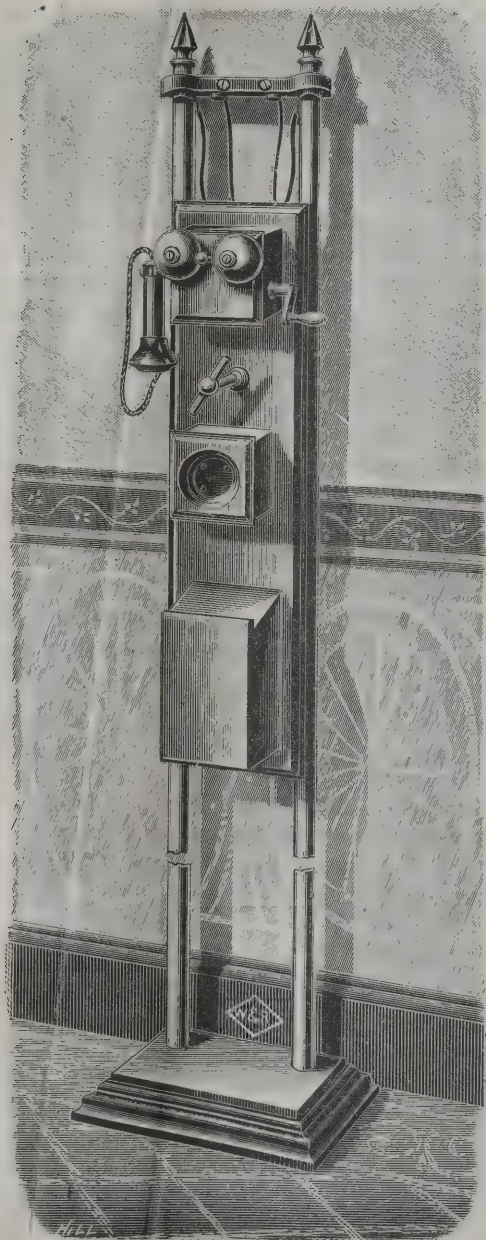

IN an action which took place last week in Manchester, for the recovery of the agreed cost of a small installation, the defence mainly rested upon the fact that as a few lamps went wrong in one portion only of the works, the installation was bad altogether. The faulty portion was in the bleaching room, where "chlorine" is freely evolved, and no notice appears to have been given to the contractors that there were unseen dangers. The plaintiffs, as will be seen from the published report, obtained the verdict. Now, this is not the first case, by many, where installations have failed in bleach and other works where "chlorine" is evolved. The action of the acid in the damp rooms is very rapid, all fittings go at once, and, in general, the insulated wire is attacked and the conductor destroyed. Sufficient care does not seem to have hitherto been employed in such works; and if the material used has been good and suitable, the manner in which it has been fixed has left it open to the attacks of "chlorine" and the speedy failure of the circuit. For such circumstances, special fittings and special wire are required, but of what kind and quality has not yet been precisely determined. Nevertheless it is difficult to understand what method of reasoning could possibly have induced the jury to arrive at its conclusion. On the face of it the evidence seems to have been as clear against the plaintiffs as one could well conceive; therefore we can only assume that the jury was influenced by facts not made public, or that the statements of Mr. Fawcus, the manager of a rival company, were considered to be of a biassed nature. In all cases of this kind it would be well to avoid bringing forward testimony which is not of a strictly impartial character.

Telephone Troubles  
from Outside Circuits.

**ADJUSTABLE TELEPHONE TRANSMITTER.**

THIS instrument is intended to enable persons of varying stature to adjust the transmitter of a telephone to the particular height most suitable to them. By the turning of a handle the carriage to which the ordinary instruments are attached can be moved up and down to any required point, and, by continuation of the brass rods through the floors of a building, it is possible to make a single telephone to serve for two or more floors. The connecting wires are of course long enough to allow of considerable extension.

Any type of transmitter can be equally well employed, as it is simply attached to the travelling carriage of the instrument, which also carries the bell and battery as shown.

Some five years ago we used an adjustable transmitter in our own offices, although not designed in the form here shown, which is controlled by Woodhouse and Rawson United, Limited.

**NEW DRILLING MACHINES.**

IN our issue of June 27th we referred to a new machine for drilling square, hexagonal, octagonal, or polygonal holes. We now publish a description of this machine, which has been invented by Messrs.

Ainley and Oakes, and perfected by Messrs. Tyler and Ellis. The original machine is similar to an ordinary drilling machine in the manner in which the spindle is driven and automatically fed downwards. The spindle, however, consists of three concentric parts. First, the outer sleeve carrying a bevel wheel, and driving the intermediate sleeve by means of a keyway and feather. Second, an intermediate spindle, having a set of five cams or cardanic circles formed upon each of its ends. There is a set of cams for each size of hole to be drilled. Third, an inner spindle carrying the tool and capable of being fed downwards either by hand or by an automatic feed, similar to the sliding spindle of an ordinary drilling machine.

The bearings or guides for the spindle consist of flat plates of hard steel made in halves and capable of being adjusted by right and left-handed screws, and suitable gearing is provided with handles and clamps. These plates are four in number, the two inner having round holes and engaging with the circular part of the spindle for drilling round holes. These are run back when the machine is drilling square holes, and the upper and lower plates, which have square holes in them, are screwed up so as to engage with the cams and give the required motion to the spindle. The pair of cams with which the square plates engage is determined by the position of the intermediate spindle, which may be raised or lowered by a hand lever and lifting gear.

This lever works in a quadrant, and is provided with five notches corresponding with the five sizes— $\frac{1}{2}$  inch to 1 inch—of holes which the machine can drill. The cams are set out as follows:—A square hole is made equal to the hole to be drilled. From any point in one side of the square, an arc of a circle is described with a radius equal to the side of the square. From the points where this arc intersects the sides of the square, other equal arcs are described completing the curve triangle. The square in which the cam is to revolve is then drawn, and from each of the vertices of the curve triangle two arcs are described which complete the figure. The point of the tool, which cuts with one edge only, must be situated beneath one of the angles of the triangle, and a different tool used for each size of hole.

In Messrs. Tyler and Ellis's improved machine, the spindle moves about the centre of a ball joint, the top end only being provided with a roller or wheel which travels round the inner edge of an annular template, being pressed outwards by a pair of spiral springs. The inner spindle carrying the tool serves a different purpose to that of the Ainley-Oakes machine. Here by lowering it, the size of the hole drilled can be varied with the greatest accuracy, while to drill a parallel hole, the whole head of the machine is lowered, moving in guides in the main framing. The templates can be easily changed, and any desired shape of hole cut. The tool is also so made that its cutting edge terminates on the centre line of the spindle, and is suitable for any sized or shaped hole. Both machines are capable, by the fitting of a cranked tool in the holder, of finishing and shaping the outsides of objects. The holes made by the machines are quickly and accurately drilled.

**IMPROVEMENT IN RAILWAY SIGNALLING APPARATUS.**

AN improved signalling apparatus for railways has recently been brought under our notice. Its object is to stop railway trains during foggy or snowy weather when the distant signal is at danger, and to dispense with the use of ordinary fog signals, and therefore with the men usually employed to place them upon the metals. The apparatus consists essentially of three parts. The first is a telescopic spring box platform placed on the ground in the centre of the 4-foot way; the second comprises an electric contact roller placed underneath the headstock of the engine; and the third is an electric bell and disc fixed on the footplate or engine platform. The telescopic spring box platform is attached to the sleepers, and works in conjunction with the ordi-

nary outdoor signals. It consists of two wooden boxes fitting telescopically inside one another, the outer or upper box having an overlapping lid resting upon two bent springs. Two similar springs are fixed at their upper ends to the underside of the overlapping lid. When the outer box is depressed in the manner to be subsequently explained, the lower ends of the two latter springs form an electric contact by being forced down upon a metal plate carried upon two supports. This act of making contact causes a current to flow through two wires connected with the metal plate, and to sound a gong attached to a suitable signal post erected in the 6-foot way. Upon the central part of the underside of the before-mentioned lid are fixed two brackets, to which is attached, by means of a pin, the upper end of a wire chain or cord. The lower end of this chain passes over two pulleys, and is connected to a pivotted quadrant which communicates by suitable leverage with the signal arm.

The electric contact roller consists of a roller mounted upon a hollow shaft, fixed in suitable bearings formed in the two arms of a forked metallic piece rigidly held by two springs, and having a shank which is bolted under the headstock of the engine. The roller is weighted at one end, and turns loosely upon the hollow shaft which carries a circular core of wood. This core has a portion of its upper part cut away, forming a flat surface which carries two metal bars with which a circular spring bearing against the core and arranged excentrically establishes a contact whenever the roller accomplishes an entire revolution. The two metal bars are connected at each end with two wires passing through the hollow shaft and leading respectively to the battery and to the bell arranged on the footplate of the engine.

The third apparatus comprises an electric bell, an indicator or disc connected with the bell by suitable springs, a cord to raise the indicator or disc, and a battery by means of which the bell and disc are operated when the contact roller passes over the spring box platform. It may here be mentioned that the latter platform is by means of the ordinary signal wire depressed so as to be level with the ground when the weather is clear and the signal open, and is raised during foggy or snowy weather, when the signal is moved to danger. In summer time the signal may be entirely disconnected from the platform which is then permanently held in a depressed condition, or the signal may be continuously operated in conjunction with the spring box platform for ordinary signalling purposes, whatever may be the state of the weather.

It may be well to explain the working of this apparatus. When the locomotive passes over the telescopic platform, the upper box is depressed by the contact roller, the circuit is completed, and the bell on the footplate of the engine is caused to ring, and the disc falls into the position of danger. The bell continues to ring and the disc remains at danger until the engine driver pulls the cord, thus interrupting the circuit and raising the signal to its safety position. Simultaneously with the depression of the platform, the second electric circuit is completed and the gong on the signal post sounds.

This system of signalling has been invented by Mr. J. A. H. Child, of East Greenwich, and Mr. J. Emery, of Erith. It has now been in operation on some sidings on the South Eastern Railway at Erith, for nearly a year, and has given complete satisfaction.

**Dissolution of Partnership.**—Mr. Wilhelm Lahmeyer, partner in the Deutschen Elektrizitätswerke zu Aachen (Garbe, Lahmeyer & Co.), retired from this firm on the 1st inst. The business will be carried on as usual by Mr. H. Garbe, but Mr. Lahmeyer will still have an interest in it. The reason for his withdrawal is to enable him to devote more time to the working out of inventions relating to central station lighting and the transmission of power. He purposes, therefore, to establish a new firm, which will work in conjunction with the Aachen firm.

## COMMUNICATIONS FROM AUSTRIA-HUNGARY.

[FROM A CORRESPONDENT.]

THE Metropolitan Board of Works at Buda-Pest has at last agreed to grant the local tramway company a concession for laying down a trial line for the use of the Zipernowsky vertical system (already described in full in your journal), and the grant of a permanent concession for lines on this principle will depend on the results obtained on this trial line. It is to be hoped that electrical and engineering specialists will soon have the opportunity of learning the practical value of this interesting construction.

Meantime, the Buda-Pest electric City Line, laid down by Siemens and Halske, is making constant progress in the construction of new lines. It has already at its disposal a very extensive net of lines, and has consequently been requested by the municipality to introduce transfer tickets between the different lines. This request, however, has been declined, as the proprietors have not at their disposal the number of vehicles required for this service.

The first electric tramway in a Hungarian provincial town will shortly be commenced in the celebrated Hungarian watering-place Herkules-Bad. The Royal Hungarian Minister of Commerce has granted to Victor Lorenz, Engineer, the concession for the technical preparations for an electric line leading from the railway station Herkules-Bad to the watering-place of the same name. The concession is for one year.

The erection of interurban telephone lines makes considerable progress in Austria-Hungary, especially as regards the connection of provincial towns with each other. A telephone line has been recently arranged between the little towns Kásmark and Leibritz, which was put in action on the 16th inst.

Between Vienna and Prague, a second interurban telephone net is to be introduced, since the telephonic intercourse between these two towns has become very active. The new line is to be carried through the towns Brünn and Kolin.

The parish authorities of the Hungarian village Zichyfalva have resolved to light the streets of the place electrically. The installation is to be combined with the illumination of a steam mill situate at the distance of 1½ kilometres, so that the Dutch Colonisation Company, who are the proprietors of this mill, are to erect the installation at their mill and to supply the power from their steam engines. About 50 glow lamps will be furnished to private consumers. The entire installation is calculated for 150 glow lamps.

In the Bohemian town Teplitz, where the agreement with the gas company expires next year, a municipal electrical station is to be erected, for which several English and German and two Austria-Hungarian firms are tendering.

The Commission of Management of the Technological Trade Museum in Vienna has resolved to create a special school for electrotechnics with theoretical and practical instruction and a four-years' course of training. Its object is to train young men, having a sufficient preparatory education, as workmen of superior grades, foremen, &c., for electrotechnical works, lighting installations, &c. This special school will be the first of its kind either in Austria or Germany; it will possess a complete and excellent equipment, and it will be under the influence of a special committee of eminent practical men. If it is sanctioned by the Minister of Public Instruction, the first and second session of this school will begin in October next, the third on October 1st, 1891, and the fourth on October 1st, 1892.

A similar school, though on a more limited scale, has existed, for some years, in the Royal Hungarian Trade School at Kaschan, under the special management of Prof. T. F. Weyde. It is provided with a small electrotechnical workshop, which enables the pupils to become electrotechnicians by means of actual work.

The Vienna International Electric Company, which is to open in November the great electrical works, supplies provisionally current for illuminating the Pacher restaurant at the Vienna Exhibition of Agriculture and Forest Service, and for working a mill erected there by Ganz & Co., which is driven by an alternating current motor at the distance of  $1\frac{1}{2}$  kilometres from the central station.

## ALTERNATIVE PATH EXPERIMENTS.

By Dr. OLIVER LODGE.

I AM somewhat surprised at the tone of controversy adopted in places by Mr. S. A. Varley in your last issue, but as he has asked repeatedly for a re-statement of my explanation of the "alternative path experiments," I give it in what I imagine to be its simplest possible form.

The experiment consists in discharging a Leyden jar through a metallic circuit, two points of which are brought very near together, and observing the conditions under which sparks occur across the air between these points.

The explanation of the spark is as follows:—When a battery, or any form of current-propeller, is used to send a current,  $C$ , through a resistance,  $R$ , the difference of potential between the ends of that resistance is  $RC$ ; and if the current be strong enough, and the resistance high enough, this difference of potential may attain such value as can break down a determinate width of air gap.

In the case of a Leyden jar discharge, the current while it lasts is very strong, and the obstruction offered by a wire is very great, hence the conditions needed for a spark are likely to be satisfied.

The length of this spark (which I have elsewhere called a B spark, or a derived spark) is directly proportional to the maximum strength of the current passing, and to the impedance of the portion of the circuit intervening between the two points of derivation. The latter factor (impedance) depends directly on the frequency of oscillation of the discharge, as well as on the length and shape of the circuit; the former factor (current strength) depends on many more or less obvious things, but it depends also on the damping coefficient of the oscillations, in a way which at first sight might not be expected because of the fact that a current does not attain its maximum value till a quarter period has elapsed since the commencement of discharge (just as the swing of a released pendulum does not attain its maximum velocity till a quarter period after it has been let go); and this time though short, is long enough to permit some dissipation of energy, especially when thin iron wires are included in the circuit.

Applying this theory to my quantitative experiments they are numerically explained; and so, until some fresh experimental evidence in a disturbing direction is adduced, I see no good reason for re-opening the question. I have hitherto failed to see any such evidence included among Mr. Varley's allegations and surmises, and I really do not know why he declines to accept it, nor why he seems to feel some personal grievance in the matter of its adoption.

I am very willing to consider and answer any valid argument against the truth of such modern views concerning electrical phenomena as I have in various places endeavoured to expound, but until there is something substantial to attack, it is not much good keeping one's hand in by pummelling straw. The only point brought forward by Mr. Varley which seemed to present some plausible semblance of difficulty, viz., that about electric welding, I discussed, principally for its own sake, in the columns of your contemporary *Industries* for June 27th.

## CONNECTING LIGHTNING CONDUCTORS TO GAS AND WATER PIPES.

PROF. L. WEBER has an article in the *Elektrotechnische Zeitschrift* of July 4th, in relation to this subject. He says Prof. Lodge's investigations were restricted by two presuppositions, viz., that the duration of a flash is very brief and something like a millionth part of a second, ordinarily, and that the discharge is oscillatory; consequently the only inference that could be drawn from them is, that self-induction may be best avoided by exchanging the solid conductor for a flat or a hollow one, and by making the conductors branch as much as possible; further, that the best means of diminishing the dangerous spreading of the fluid, which is due to self-induction, is to augment the conductor's capacity, and that the most practicable method of doing this is to connect the conductors to the gas and water system.

Now, says Prof. Weber, there is indubitable evidence that the duration of a flash may vary within very wide limits. There are flashes which do indeed last only for the millionth part of a second, such as those observed by Dove with his revolving disc, and these are badly described as brief duration flashes. There are, besides, flashes whose duration is  $\frac{1}{2}$ -1 second; these are called long-duration flashes, and are further distinguishable from the others by their ruddy tint.

It is extremely probable that it is only long-duration flashes which have the power to communicate fire, although violent mechanical and physiological disturbances may be occasioned by those of brief duration. That the latter may possess oscillatory characteristics can, by analogy with the artificial sparks produced with a battery, and on the authority of Prof. Lodge's observations, be accepted; but that they possess them normally has yet to be proved.

That there may be long-duration flashes without these characteristics has been proved by photographs taken by the writer last summer, and described in the reports of the Berlin Academy. That long-duration flashes can also be oscillatory, he is not as yet in a position to deny, but the probability is against it. Naturally a multitude of variations on these two extreme types may be conceived.

It will now be seen, says Prof. Weber, that Prof. Lodge leaves untouched a class of flashes which is of long duration and not oscillatory, as well as another class whose characteristics are perfectly established. His investigations only take account of flashes whose characteristics are hypothetical, and their only practical value, therefore, is to confer fresh importance upon one of the oldest established types of conductor construction that, viz., in which the conductors are attached to the gas and water systems, and, possibly, to throw into relief the superiority of Melssen's system over that of Gay-Lussac.

The plan of construction for lightning conductors, the sufficiency of which has been made manifest by a century of use, will, Prof. Weber thinks, undergo no sensible alteration through Prof. Lodge's investigations, but rather will its usage be confirmed in every essential particular, and the difficulties which stand in the way of its wider adoption removed.

## AUSTRALIAN NEWS.

(FROM A SYDNEY CORRESPONDENT.)

THOUGH Sydney itself is very much behind its neighbours Melbourne and Brisbane, in the matter of central stations, still in the matter of electric lighting of country towns, New South Wales is much ahead of either Victoria or Queensland. As your readers doubtless know, Tamworth has for some time had the electric light installed by Messrs. Harrison & Whiffan, for the Crompton Co. The installation at the town of Young has just completed its anniversary, and the town authorities

have taken it over in good working order from the contractors, Messrs. H. H. Kingsbury and Co. The town of Moss Vale also has a small plant for public lighting, as also has Enfield. The lighting of the towns of Lambton and Penrith are proceeding apace under the hands of Messrs. H. H. Kingsbury and Co., who have secured the contracts for both places. The plans are prepared for the lighting of Katoomba, a small town in the Blue Mountains, the contract for which has also been secured by Messrs. H. H. Kingsbury & Co., and the wiring of several of the houses already completed. Tenders have been asked for the lighting of Redfern, a Sydney suburb, and the towns of Newcastle and Grafton. The towns of Tenterfield, Maitland, and others, and the suburbs of Ashfield and Campbelltown are all considering the question of electric lighting in real earnest. Taking things all round, it looks as if we were going to have a boom in electric lighting in New South Wales. An electric tramway is projected in Sydney, on the Thomson-Houston system, and orders have already been sent to America for the necessary equipment. There are several well-known English electricians located in Sydney just now, viz., Mr. Elwell, of Elwell & Parker, who has just given very good evidence before the Public Works Committee on the subject of electric trams; Mr. Callender, of the Callender Bitumen Company; and Mr. J. R. Williamson, late managing director of the Edison-Swan Company of Manchester, and who has now established himself here as managing director of the Williamson Electric Engineering Company. The want of a good consulting electrician has been felt here for some time, and Mr. Robert Oxlade, late of the Eastern Extension Company, and still more recently electrician to Messrs. H. H. Kingsbury & Co. and designer of the Young installation, has thrown himself into the breach, and already his action seems to be well appreciated. At a recent meeting of the N.S.W. Engineering Association a paper on Mr. Van Rysselburghe's system of distribution by "hydro-dynamos" was read and discussed. The reader of the paper must have had a rather uncomfortable time of it, as out of about a dozen speakers not one found a word to say in its favour.

The installation at Young is on the Thomson-Houston alternating system, and comprises three 500-light 16-C.P. dynamos of 1,000 volts potential, the transformers reducing this to 52 volts for the house circuits. There are two 25-H.P. Fowler engines, one only of which is being used at present to drive two dynamos.

The streets are lighted by 10 lamps, each containing six 16-C.P. incandescent lamps, and about 60 lamps of over 16-C.P.

The rates at present charged by the municipality are as follows:—One light, per annum, £1 10s.; two lights, £2 15s.; three, £4; four, £5 5s.; five, £6 10s.; six, £7 10s.; seven, £8 10s.; eight, £9 10s.; nine, £10 15s.; fifteen, £15 5s.; all over this number 10s. per annum each.

This is about equal to gas at 3s. 2d. per 1,000 c. feet, and gas cannot be produced in Young under 12s. 6d., which shows well for electricity in New South Wales. At present only about 700 lamps are being used.

The plant being put in at Penrith consists of two 30-N.H.P. compound Robey engines, driving two 650-light Thomson-Houston alternating dynamos.

At Lambton, two 25-N.H.P. Fowler engines are being used, with two 650-light Thomson-Houston alternating dynamos.

Tamworth at present has only a capacity of 500 20-C.P. lamps, the majority of which are used in street lighting, the dynamos being driven by two 12-N.H.P. semi-portable engines made by John Fowler and Co.

By the *Mariposa*, which arrived last week from San Francisco, came materials for starting an experimental line on the Thomson-Houston system. The cars are to arrive by next steamer.

Tenders for the supply and erection of plant for electric light at Bullock Island, Newcastle, gave some curious results. There were eleven tenders, ranging

from £2,720 to £6,275, there being over £1,000 difference between the lowest tender and the next lowest. Crompton & Co., Ganz & Co., Siemens Bros., The Brush Company, and the Manchester Edison and Swan were amongst the tenderers, the rest being local companies.

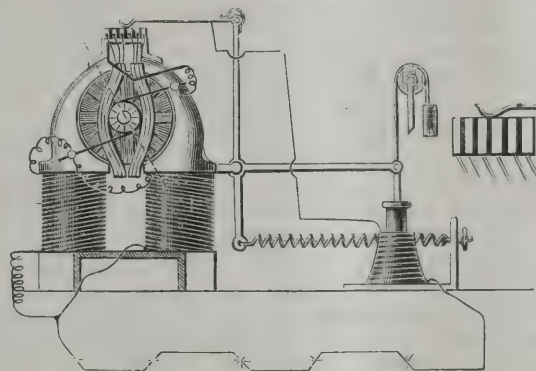

With regard to isolated electric lighting plants, the offices of the *Daily Telegraph* and of the *Evening News* are lighted, the latter having a fine set of Crompton-Howell cells; all the latest hotels have, of course, had the new illuminant installed. Circular Quay, the busiest part of the harbour, from which go the Orient, P. & O., Messageries, Maritimes, &c., mail boats, and most of the ferry boats, is well lighted by means of Brush arc lamps (shortly to be replaced by Brockie-Pell), as is Cowper's Wharf, Woolloomooloo, where the American mail steamers are wharfed.

June 1st, 1890.

### NEW REGULATOR FOR CONSTANT CURRENT DYNAMOS.\*

THE method of regulating constant current machines, illustrated diagrammatically in the cut, consists in the application of a set of demagnetising or opposing coils around the armature, in combination with a device for varying the current in the coils or varying the number of convolutions through which the current passes.

In this machine the core of the armature contains so much iron as not to become saturated when under load. The field magnets are wound so as to operate nearly, if not quite, to saturation. The field coils are connected in multiple, and are placed, as shown, in the main circuit. In order to prevent, as far as possible, sudden changes in the magnetism of the fields, Prof. Elihu Thomson, who is the inventor of the regulator, proposes to make the field magnetism the resultant of the magnetising effect of two or more field magnet coils. These are to be placed in separate circuits having different

self-induction. The difference of self-induction in the two coils of the branches may be obtained by giving a different number of turns to the coil. The current which passes in the two coils may be made equal by having the coil resistances equal, or by adding resistance to the coil branch which has the least resistance, as is indicated to the left in the diagram. The main portion of the regulator consists in the stationary set of coils wound about the armature. These when in circuit convey current in a direction to neutralise or tend to neutralise the induced magnetism of the armature as produced by the field magnets. It is only requisite that this opposing action have a value such that under any conditions the machine yields its normal current and an electromotive force just sufficient to maintain that normal current. A moving arm at the top slides over a set of contacts connected with the sections or successive turns of the coils, as shown. This contact arm is controlled by a lever, actuated by a magnet core against the counter action of a balance weight and spring. The last-named coil is made responsive to

\* *Western Electrician.*

the variation of the main current. The connections are such that when the current on the circuit increases above the normal, the arm at the top is shifted to bring into action the stationary coils about the armature. This produces an effect which opposes the effect of the magnetism of the field upon the armature, and cuts down the electromotive force. When the current falls, the regulator acts to cut out turns of the stationary coils. This gives stability of current strength under varied conditions, either with all the lights in circuit or with a lessened number.

### THE BIRMINGHAM BRISTOL ROAD ELECTRIC TRAMWAY.\*

THIS tramway forms one section of the Birmingham Central Tramways Company's system, and extends from the city along Suffolk Street, Bristol Street, and Bristol Road to Bournbrook, being three miles in length, and double line throughout. For about twelve years the above route was worked on the 4 feet 8½ inch gauge as a horse tramway, but having become very dilapidated and dangerous, it has recently been reconstructed to the same gauge and in a similar manner as the remainder of the company's lines, in connection with which a generating station has been erected at Bournbrook for the purpose of enabling the accumulator system of electric traction to be adopted.

The charging station, 75 feet long and 63 feet wide, where the cars are relieved of the exhausted batteries and supplied with charged ones, forms the front of the dépôt, and contains four lines of rails, which run through it into the car-shed behind, which is 100 feet long and 63 feet wide. The whole of the trucks in the car-shed and charging station are provided with pits, so that an examination can be made of the motors, gearing, and brakework, wherever the car may be standing. For the removal of the cells to and from the cars there have been constructed four hydraulic elevators, with eight shelves to each elevator, capable of storing sufficient cells for sixteen cars, besides which additional storage is provided in the accumulator room, where platforms are fixed to accommodate sufficient cells for two extra cars. These can be charged at the same time as the cells on the elevator cages, which are not closed in, but are open all round, so that the cells may be thoroughly under control and examination. Underneath the whole area occupied by these elevators is a chamber which facilitates examination of the cylinders, rams, and connections, and enables the cages to fall below the floor level.

The engines and boilers are in duplicate, and each boiler is capable of generating steam for one engine, each engine being guaranteed to deliver 100 horsepower on the flywheel. The two boilers are of steel, multitubular, of the "economic" safety type, 12 feet 6 inches long and 7 feet 6 inches diameter, each with two flues 2 feet 4 inches diameter.

The dynamos, two in number, are in the same room as the engines, and are duplicate of each other. They are of the Elwell-Parker continuous current type, shunt wound, each to give 120 volts 500 ampères, at an approximate speed of 540 revolutions per minute, and do the whole of the work, charging accumulators for twelve cars, the lighting of the dépôt, and the current supplying an 8-unit motor, which drives the machine tools. Dogs and slides are provided for tightening up the belts when required. The brushes are arranged to bear lightly upon the commutator, and are carried upon a rocker, which rotates to permit its being set in the best position, the brush holders being fitted with insulated "hold-off" catches. Two spare armatures will be provided to fit either of the two dynamos. Resistance coils and switches are provided for maintaining a constant electromotive force at the dynamo terminals.

From the positive terminals of the dynamos connection is made to the main switchboard, also in the engine room, provided with two main Cardew voltmeters, ammeters—600 ampères each—main dynamo switches and fuses, and distributing switches and fuses. On leaving the main switchboard the cable rises up to the tie-rods of the roof, along which it is conducted in a hard wood casing to the switch room, adjoining the accumulator room and the hydraulic elevators into which the cable drops, and is distributed among five regulating boards, one for each of the elevators and one for the accumulator room. Each board is fitted with ammeters, switches, fuses and adjustable resistance coils sufficient for eight circuits, *i.e.*, the eight shelves of the cage or hydraulic elevators, and carries up to 50 ampères. The resistances are arranged so as to be capable of maintaining a constant charging current through each set of cells. A voltmeter and multiple pole switch are provided to each board for measuring the electromotive force of any set of accumulators. From one of these regulating boards connection is made with the platforms in the accumulator room, the leads from the remaining four being taken overhead along a division wall to the vertical copper strips, attached to the castings guiding the hydraulic cage elevators. These vertical strips run from top to bottom of the guides, and are electrically connected to the batteries on each shelf by spring contact blocks attached to the cage, rising or falling with it, and sliding against the copper strips. After the current has passed through the batteries on the cages, it returns by means of similar copper strips on the opposite guides to the negative lead, then through the negative terminal fuse blocks, and on to the dynamo. There are also provided portable voltmeters for testing single cells, tachometers for indicating speed of dynamos, and hydrometers for testing the specific gravity of the acid solution. The accumulators, secondary batteries, or storage batteries, are of the Elwell-Parker type, contained in vulcanite cells filled with dilute sulphuric acid, and are composed of thin lead grids, filled with a paste of red lead or minium, and placed vertically in the cell. There are 19 grids or plates in each cell, 10 negatives and 9 positives, each plate being about 8½ inches by 6½ inches. The plates are kept apart by means of vulcanite insulators, and sufficient space is left between the plates to prevent their being short-circuited in case any of the paste pellets should happen to fall out of the perforation of the grids. When placed in the car, or when being charged, eight cells are placed in a teak tray and permanently connected, three of such trays forming one of the four groups into which the whole battery—when in the car—is divided for controlling purposes. There are 96 cells to each car, giving a total electromotive force of about 192 volts, and requiring a current of about 35 ampères to charge them, an operation which lasts about 10 hours. The hydraulic cage elevators are so constructed that the cells can be removed any time, and the operation of charging is commenced by the automatic connection, made directly the trays are removed from the cars to the shelves of the elevators. The lighting of the sheds and shops is by means of 16 candle-power incandescent lamps distributed throughout the building, with wall plates for connecting with portable hand lamps. Two 200-candle-power lamps are fixed over the entrance to the charging station.

The cars—twelve in number—have been built by the Midland Carriage Company at Shrewsbury, the electrical and mechanical fittings being supplied by the Electric Construction Corporation from their works at Wolverhampton. The cars—which are very similar in appearance to the cable cars belonging to the same company—are 6 feet 3 inches wide and 26 feet 6 inches long, about 4 feet 6 inches at each end being occupied by the platforms, and are constructed to carry 24 inside and 26 outside passengers. They are carried on two bogie trucks, about 15 feet between centres, the framework being of I-iron strengthened by two King trusses. On the top of the cars reversible garden seats are provided, and inside, the usual longitudinal seats with a passage down the

\* Abstract from an article in the *Engineer*.

centre. There are six trays on each side of the car, and each tray holds eight cells, there being 96 cells altogether. The cells are of vulcanite, and the trays of teak, each tray carried on three runners fixed to the car floor. The cells in each tray are permanently connected up in series, and the positive and negative terminals are connected to brass plates attached to opposite ends of the tray. Between each pair of trays is fixed a spring copper contact block, V-shaped, screwed to the floor of the car, with the apex of the V pointing outwards, the wings of the V spreading laterally. When the trays are pushed into the cars, the two tips of the V pieces come into contact with the brass plates on the ends of the trays, and so the whole of them are automatically connected up. The 12 trays—96 cells—are arranged in four groups of 24 cells each, the whole of the cells in each group being permanently in series, and the four positive and four negative terminal leads are brought up to the switch used by the driver of the car, by means of which the four groups may be connected up with the motor in six different ways:—No. 0, all the groups separate and disconnected; No. 1, all the groups in parallel, but not connected with motor; No. 2, the four groups in parallel, all the positives being connected together and with the positive terminal of the motor, and all the negatives together and with the negatives terminal; No. 3, half the groups in series and half in parallel; No. 4, one group is cut out and the other three groups are connected in series; No. 5, the whole four groups in series. Thus it will be seen that the whole of the cells are always in use when the car is in motion, fair uniformity of discharge being maintained. When the switch handle is at the extreme end, the whole of the batteries are on open circuit, disconnected from each other and from the motor. On being moved into the first position, the batteries are all connected up and ready for work, but not connected with motor. This position tends to equalise the batteries (No. 1). The second position connects the batteries with the motor, but only gives one-fourth of the total electromotive force, and would be used probably when travelling on the level with a light load (No. 2). The third position gives half the total electromotive force (No. 3). The fourth position gives three-fourths of the total electromotive force, one group being cut out (No. 4). The fifth position gives the total electromotive force of the whole of the 96 cells, and would be used in going up-hill with a heavy load (No. 5).

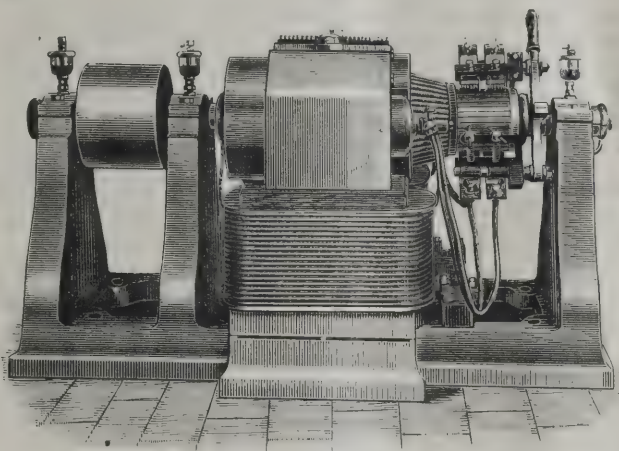

The motors are of the Elwell-Parker type, double limb, series wound, and run with 140 revolutions, but a velocity of 700 revolutions per minute is required to maintain a speed of eight miles per hour. There is only one motor to each car, carried on one of the bogie trucks by means of an aluminium, brass, or steel frame, which has three points of support, two being rigidly fixed on one axle of the bogie, and the other resting on the second axle, through the intervention of a strong helical spring. Thus it will be seen that the motor and its appendages are entirely independent of the oscillation of the car, due to variations of load. At one end of the armature are the commutator and brushes, and the other end carries a pinion, which gears right and left into two spur wheels carried by countershafts on a brass frame. On these same countershafts are fixed additional pinions, which gear into spur wheels on the two axles of the bogie, and thus the motion of the armature is gradually reduced to the speed required for the car, the proportion being about  $6\frac{1}{2}$  to 1. All the gearing is done by helical teeth.

The switch, by means of which the driver controls the current, and therefore the car, is placed on the car platform just beneath the steps, and is quite out of the way of the passengers. The lead, &c., joining the cells up to the switch, are enclosed in a teak matchboard casing, the switch being placed on the top of the casing. The part of the car floor over the motor is removable. The cars are lighted by two 16-candle-power incandescent lamps—one at each end. A powerful brake is provided, which grips the whole of the eight wheels at the same time, and there is also an auxiliary brake attached.

### THE PREECE DYNAMO.

IN the Preece dynamo, to which we referred in a recent issue and of which we now give an illustration, the bed-plate and brackets are one complete casting. The plummer blocks are fitted with adjustable phosphor bronze bearings, and each bearing is fitted with a sight feed lubricator.

The magnet yoke, which is cast in one piece, is let into a recess in the bed-plate, and the pole pieces are separate castings bolted to the magnet yoke. The field coils are wound upon separate shells with zinc flanges, and are interchangeable for all machines of the same output. The armature is built up with charcoal iron discs insulated from each other with a specially prepared varnished paper, and are held in position on the shaft by two insulated bolts passing through the driving

end plates which are firmly keyed to the shaft. The armature core is ventilated internally by suitable divisions being left at every 2 inches between the plates. The armature is wound one layer deep, with 19/17 strand braided cable, and connected up to a 60-part commutator, there being one complete turn per commutator bar.

The armature on the pulley side is provided with a blower to send a current of air through the pole pieces and prevent an accumulation of dust; both ends of the armature are protected with brass shields fitted to the pole heads. The brushes are made of soft brass wire and their pressure upon the commutator is regulated by thumb screws.

At a speed of 800 revolutions per minute the E.M.F. is 110 volts, and the current at full load, 250 amperes, there being no sparking. The rise of temperature after 10 hours continuous run is said to be 40 degrees on the armature conductors, and the field coils 30 degrees Fah. above the temperature of the air.

**A Locomotive Telephone Signal.**—In order to show that the telephone may be adopted as a danger signal on railway lines, a locomotive telephone signal was recently tested by the Baltimore and Ohio Railroad Company on about three miles of its track. The apparatus consists of a single iron rod running between the rails, supported on insulators, and an electric gong connected with a battery carried on the locomotive. The connection between the gong and the iron rod is made by means of an insulated wire from the gong to a wire brush underneath the locomotive, which touches the rod. Two trains approaching each other on the same track will complete a circuit and warn each other by ringing the gong. The gongs on the two trial trains commenced ringing when they were about two miles apart; the telephone mouthpiece was then switched to the wire, and conversation was carried on between the two drivers. The apparatus is stated to have worked very satisfactorily.

## LONDON COUNTY COUNCIL AND OVERHEAD WIRES.

## OBJECTIONS OF LOCAL AUTHORITIES.

ON Tuesday last, at the weekly meeting of the London County Council at Spring Gardens—Mr. Alderman HAGGIS in the chair—Mr. NATHAN MOSS, the Chairman of the Fire Brigade Committee, submitted a report containing the following statement:—

"We have to report with respect to the 200 additional fire-alarms authorised by the Council on 30th July last, that we have ascertained from the Post Office that the average annual cost of the call-points on the north side of the Thames will be about £9 12s. 8d. As this sum is less than the amount (£10) which we estimated, we have given directions for the work to be put in hand. As regards the additional fire-alarms south of the Thames, however, we have been informed by the Post Office that, in consequence of the objections of the local authorities of certain districts to the erection of overhead wires, underground pipes would have to be specially laid for the wires in such districts. The annual cost of the fire-alarms would, in consequence, be increased in some cases as much as four and five-fold. In fact, in one instance, at Tooting, a single call-point would cost more than £53 a year. We cannot recommend the Council to pay such a large sum for these fire-alarms, and we are accordingly unable at present to order the establishment of more than 20 out of the 52 which we proposed to have fixed in the part of London referred to. The average annual cost of these 20 will be £10 5s. 6d. each. The following are the stations which will not have their complement (10) of fire-alarms, viz.: Kennington, Tooting, Clapham, Battersea, Shooter's Hill, Blackheath, Lewisham, Camberwell and West Norwood. We may mention that we propose to have a fire-alarm fixed in Blackwall Lane, East Greenwich, the Vestry of Greenwich having asked that such a means of communication with the brigade might be afforded to the inhabitants of the locality."

Mr. BEACHCROFT wished to know whether it was the policy of the Fire Brigade Committee to encourage the erection of overhead wires?

Mr. MOSS stated that the matter referred to in their report was a rather serious one, so far as the committee were concerned. They felt that it was not desirable to incur the extra expense which would be necessary for the laying of underground pipes. Therefore, under the circumstances, they would have to forego placing some of the fire alarms, so long as the parochial authorities were so strongly opposed to overhead wires.

Mr. BEACHCROFT hoped the Council would not encourage the abominable example set in some cases of erecting overhead wires. (Hear, hear.) He hoped the committee would bring forward a special report on the subject.

## ANOTHER ELECTRIC LIGHTING BILL.

Mr. CHARLES HARRISON, as Chairman of the Parliamentary Committee, reported as under:—"We understand that another Electric Lighting Confirmation Bill is to be introduced, and that it will contain orders affecting the City of London. We were authorised on the 3rd June last to present a petition against any order which does not comply with the Council's resolutions of the 28th January and 22nd April, 1890, and we have authorised the preparation and presentation of petitions in the event of any of the orders complying with the above-mentioned resolutions."

## NOTES.

**Cardiff Lighting.**—At a recent meeting of the Lighting Committee, a deputation from the residents of Broadway attended, to ask for better lighting of that thoroughfare. It was stated that a great many shops now empty, would be occupied if Broadway were better lighted. The deputation were told that the matter would be favourably considered. The committee next received a deputation consisting of Mr. Garcke (secretary and manager), and Mr. Deakin (local manager), of the Brush Electric Lighting Company. Mr. Garcke dealt at length on the advantages of electric lighting, and urged the committee to recommend to the corporation that they support the application of the company next session of Parliament for a provisional order to illuminate Cardiff with the electric light. The chairman said that so far as a promise or entering into any contract, the committee were not in a position to take action. The deputation then withdrew. A motion that a special meeting be called to consider the matter, and that in the meantime the Town Clerk be instructed to ascertain if any corporate bodies had obtained provisional orders, and had granted them to electric lighting companies, and if so, upon what terms; also that the engineer procure particulars as to subways in use in other towns, the laying of subways in Cardiff, and other details.

**Electric Lighting in Newcastle.**—It has been resolved by the Lighting Committee of the Newcastle Corporation, to recommend the Watch Committee to light the whole of Neville Street with five electric arc lamps, in place of 80 or 90 gas lamps.

**Electric Lighting in South East London.**—The Committee of the House of Commons has passed a Bill confirming a provisional order granted by the Board of Trade to the Electric Installation and Maintenance Company for the electric lighting of the district surrounding the Crystal Palace. The area is defined to consist of a portion of the district of the Lewisham Board of Works, and small portions of Beckenham, Camberwell, Lambeth, and Croydon. The order granted to the Metropolitan Electric Supply Company for lighting the parish of Paddington was also confirmed.

**Electric Lighting at Mirfield.**—Messrs. Lister, of Battysford, Mirfield, contemplate having the whole of their works lit up by electricity. This is the sixth firm in Mirfield which has introduced electric lighting.

**Electric Lighting of St. Pancras.**—The electricity committee reported at the last vestry meeting that some 43 tenders had been received. The committee promises to report thereon at the earliest possible date. The London Electric Supply Corporation and the Metropolitan Electric Supply Company are again making applications for provisional orders to supply St. Pancras.

**Barnsley and the Electric Light.**—Considerable discussion is taking place in the Barnsley Town Council with respect to Mr. Bromley Holmes's advice that the Westinghouse Electric Company's tender be accepted at a cost of £17,800. The *Barnsley Independent* takes up the subject warmly, and wants to know why the tender of an English company, the National Electric Supply Company, for £11,888, should not be accepted. It concludes its article as follows:—"We also think they ought to give the work to English firms, in preference to giving it to firms which are not English. The question is a wide and an intricate one; but, on the face of it, this passing over of an English tender for an American tender which is *dearer*, will require considerable explanation, we think, before it can be rendered acceptable to the ratepayers. Seeing that the idea of introducing the electric light into the borough took its rise from the desire to get an illuminant cheaper than that supplied by the Barnsley Gas Company, the policy proposed by the Town Council may surely with reason be spoken of as economy extraordinary."

**Lighting the Portman Rooms.**—Messrs. Benham and Sons inform us that they have secured the contract for electrically lighting the Portman Rooms (formerly Madame Tussaud's exhibition. The Metropolitan Electric Supply Company is arranging a special main from the Manchester Square station.

**Electric Light in Edinburgh.**—At a sub-committee of the Lord Provost's Committee of the Town Council had under discussion last Friday the question of an electric supply for the city. Some conversation took place, and it was resolved that the Parliamentary solicitor should be instructed to report upon the position of the corporation in the matter.

**Robbery of Platinum.**—At the London Sessions, July 17th, four men, named Jeffries, Hewlett, Fenn, and Price, were brought up for judgment, having been convicted at the last sessions of stealing a large quantity of platinum, valued at between £800 and £900, the property of the Brush Electric Light Company, of Belvedere Road, Lambeth. Jeffries was sentenced to five years' penal servitude, following on previous convictions; Hewlett to sixteen, Fenn to ten, and Price to seven months respectively. The police engaged in the case were specially commended for their conduct.

**Electric Traction at Birmingham.**—The official inspection of the electric tramway on the Bristol Road by the Board of Trade has been made by Major-General Hutchinson, who was accompanied by Major Cardew, inspecting officer of the Electrical Department of the Board of Trade. The inspecting officer proceeded to Navigation Street, where he boarded one of the electric cars. The journey to Bournbrook, a little over three miles in length, was satisfactorily accomplished. The car ran rapidly to the Bristol Road, and Major-General Hutchinson, who was riding with the driver, suddenly gave the order on one of the inclines to stop the car. This was done to test the brake, and from the moment the brake was applied the car barely moved a length. Major-General Hutchinson was hardly satisfied with this. In his opinion the brake should have acted with greater effect, and the car should have stopped much more quickly. On reaching the dépôt at Bournbrook the Major-General inspected the engines, the electrical machinery, the elevators, and the cars. Shortly after 2 o'clock the return journey was commenced. On the decline from Wellington Road to Belgrave Road the car was suddenly stopped, but the distance run after the application of the brake was again greater than the inspecting officer approved. When the car rounded the curve from Suffolk Street to Navigation Street the speed was increased, and the vehicle proceeded down the street at a tremendous pace. Suddenly the brake was applied and the car was once more stopped within a length. The inspecting officer was still dissatisfied. He considered the car should have been pulled up much quicker, and he had the brake tested two or three times. The inspecting officer suggested two or three alterations for the purpose of improving the efficiency of the brakes, and these Mr. Joseph Smith promised should be carried out. The inspection, which in every other respect had been very satisfactory, then terminated.

**The Western Union Cables.**—Mr. G. von Chauvin writes:—There appears to be an impression that the fire at the Western Union building in New York has interfered with the despatch of cable messages over my company's Atlantic cables. As both the Atlantic cables of my company run direct into a special office—16, Broad Street, a considerable distance from the Western Union building—no delay has arisen to our Atlantic cable traffic.

**The Dire Effects of Magnetism.**—The writer of "Table Talk" in the Birmingham *Daily Mail* had some funny things to say on Saturday last respecting the Bristol Road Electric Tramway. After assuring his readers that the electric tram dépôt at Bournbrook is a much more interesting place to visit than one might suppose, he gives this piece of advice to anyone who is about to go there—leave your watch at home. During the several inspections that have taken place recently, several gentlemen have afterwards found that their watches persistently refused to go. Curiously enough, however, whilst some had this experience others have discovered no unfavourable effect upon their "tickers." Hereupon it seems that the newspaper man sought the reason, and he relates how one of the electricians told him that this was attributable to the fact that different individuals are very differently affected by electric influence. One person, said his informant, will much more readily transmit electricity than another. He goes on:—"There is an impression which I have frequently heard expressed that passengers by the electric cars will be liable to the same sort of thing; but I am assured that this cannot be so, as the force is not generated, but merely stored in the lower part of the cars, and is completely insulated."

**Channel Telephone Cable.**—It was stated last week that experiments are being made with a view to laying a telephonic cable across the Channel. We are under the impression that tests over the existing cables have been going on for some considerable period.

**Got the Needle.**—A lady stated last week, in the columns of the *Times*, how she had been duped by a gentleman calling himself an electrician, who undertakes the removal of superfluous hairs by the agency of the electric needle. She paid a guinea and signed a cheque for £45 before operations commenced, and had not been home a week before all the hairs commenced growing again. These, she was coolly informed, were new ones, and she was impudently asked how much more money she was willing to pay. She suggests that probably an action at law would have ended in her favour, but that would have involved further expenditure, and this she did not care to incur. There are other so-called electrical curative appliances besides needles which we should like to see dealt with in the same manner in the columns of the daily Press, and perhaps we may take the above publication as a good omen.

**A Telegraph Office Destroyed.**—An explosion took place at the Western Union Telegraph Company's offices, Broadway, New York, at seven o'clock on the morning of the 18th inst., in the battery room on the sixth floor, and the flames, which immediately broke out, soon spread to the portion of the building above, including the operating room and the offices of the Associated Press, both of which were gutted, while the lower floors were drenched with water. The loss is estimated at 250,000 dollars. Only about forty operators were on duty at the time, and all succeeded in effecting their escape.

**Railway Contracts.**—Woodhouse and Rawson United, Limited, have again secured the contract for the supply of electrical instruments on the London and North-Western Railway for the ensuing year. This contract has now been held by the firm for several years, whilst it has also been awarded the contract for the supply of instruments to the Caledonian Railway for the year.

**The American Eagle.**—The *Electrical Engineer* of New York has every reason to believe that Mr. Ferranti will emerge triumphantly from his arduous labours over the Deptford scheme; indeed, our contemporary thinks that there is now sufficient evidence to show that complete success will ultimately be attained. We sincerely rejoice to note that "the courage and enthusiasm which have thus far accompanied his work may possibly be traced to the touch of Yankee blood in his veins."

**Morgan's Electric Signal System.**—We are informed that the patent rights of this invention for the whole of Europe have been sold for £250,000. Operations in connection with the practical demonstration of the system in the Brixton district are now being carried on, and instead of 12 lamp-posts, as previously reported, it is proposed to erect 36.

**Promotion of New Companies.**—As many of the electrical companies which have recently been brought before the investing public have not been floated, the bringing out of several of the proposed new companies for dealing with electric traction, welding, lighting, &c., has, according to various authorities, been postponed for the present.

**Killed by Lightning.**—The artillery barracks at Comorn, Austro-Hungary, were recently struck by lightning. The electric fluid penetrated three rooms, and threw twelve men out of their beds. Two of the men were killed on the spot.

**Pneumatic Telegrams in Paris.**—A treaty securing for the Paris suburbs pneumatic telegrams in order to correspond with Paris has just been signed between the Director-General of Posts and Telegraphs, and M. Aigoin, director of the southern tramways, the author of the project.

**Submarine Navigation.**—A Madrid telegram of last Saturday says: "In view of the recent successful trials with Lieutenant Peral's electric submarine vessel, the Minister of Marine has appointed a Commission to report upon the advisability of the Government ordering the construction of several submarine torpedo boats."

**Electrical Enterprise in Saxony.**—A concession has been granted to a civil engineer and a firm of bankers in this city, authorising them to establish a network of cables for purposes of transmission of power and electric lighting direct from some coal mines through 168 towns in Saxony to Dresden.

**Hotel Métropole, Brighton.**—The electric light fittings for this hotel, which possess certain features of novelty, have been supplied by Messrs. Benham and Froude. The principal bed rooms are fitted with very pretty portable table pillars of four distinct types, the incandescent lamps burning within opal shades covered with silk and lace, of tints to harmonise with the decorations. In the private sitting rooms and important vestibules are electroliers in brass, richly chased and burnished, having from three to ten lights each, with tinted and cut shades and rope-like down rods. For the principal suite of three large public dining rooms, what may be termed "electric sunlights" have been adopted, several being fixed within a very few feet of the ceiling of each room. They comprise a large, handsome deep inverted brass disc, embossed and highly polished, within which are a number (varying from five to ten in one or two tiers) of glow lamps, the whole being surrounded by a heavy fringe of cut glass prisms, the glittering brass and the prismatic hues giving a most brilliant, sun-like effect. This arrangement was carried out in accordance with the ideas of the proprietors of the hotel.

**The St. Pancras Vestry.**—A curious specimen of the manners and customs of vestrymen came to light at a recent meeting of the St. Pancras Vestry, when it was proposed to fill a seat on the Electric Lighting Committee in the place of a retiring member. One of the two candidates was asked if it was true that he had issued cards to the committee, recommending a gentleman who wished to introduce a new scheme, and he explained that he had known the gentleman referred to for many years, and he was one of the most eminent electrical engineers in the metropolis. He had received an invitation from him to visit an installation at Paddington that had been in existence some four years, and to bring some friends with him, and he thought that it would be very interesting to the members of the committee to see an installation in good working order, and he accordingly invited some of them. Being further asked if it was true that at the last vestry meeting he introduced several members to this most eminent electrical engineer, he replied that the M.E.E.E. had certainly sent in his card and wished especially to be introduced to Mr. Westacott. If this was blandishment, it was utterly thrown away. Mr. Westacott hotly denounced the candidate's proceedings as a scandal, especially after the committee had already accepted the services of another eminent engineer. It was a curious fact, he said, that the M.E.E.E. knew all that had taken place in committee. The rival candidate, who, it was said, had been for ten years connected with electric lighting, was elected to the vacant seat.

**Coatbridge Lighting.**—Says the *Glasgow Herald*:—The decision given in the case of the Coatbridge Electric Lighting Provisional Order is of very considerable importance. It is the first case in which an electric lighting provisional order has been opposed by a gas company on the ground of competition, and as the gas company got the worst of it, it may be assumed that Parliament has set a precedent against such opposition for the future.

**Lavoisier's View.**—M. Berthelot, a member of the Académie Française, has written a book called "La Révolution de la Chimie Lavoisier," in which Lavoisier's incorrect but historically interesting opinion as to the nature of electricity is given as follows:—"I have thought for some time that the electric phenomena, like the phenomena of combustion, are merely the effect of decomposing air, and that electricity, consequently, is nothing but a very slow combustion."

**The Electric Sugar Fraud.**—The New York Courts have given judgment in favour of the English stockholders.

**Electricity and Water Power.**—The Sheffield Water Committee, in view of the probability of the Corporation obtaining power to supply electricity for public and private purposes in the borough, has called attention to the water power connected with their wheels on the Rivelin.

**Telegraphists and the State.**—The *Electrical Engineer* of New York points to England as proving that the lot of a "telegrapher," where the telegraphs are under Government control, is not one to be envied. Our contemporary has discovered a "rumour" that the Post Office contemplates sending to America for men, and observes that the few who might possibly go would hardly be likely to find America a pleasant country to return to.

**The Columbian Exhibition.**—An influentially-signed petition, the signatures of which include all the leading men and houses in Chicago, has been sent to the board of directors of the World's Columbian Exposition, requesting the appointment of Mr. J. P. Barrett, the City electrician of Chicago, as director of the electrical department of the exhibition. Mr. Barrett is a public official without commercial alliances, and his name has frequently figured in our pages.

**Telegraphs in South Africa.**—A correspondent writes to a contemporary that the Chartered South African Company's line of telegraphs has now been completed as far as Ramoutsa. The first message transmitted over the new line was one from the Chief Ikening to Sir Sydney Shippard, Administrator of British Bechuanaland. It was as follows:—"Congratulations on telegraph office being opened here. Hope it will lead to prosperity of my people. Am doing the best I can to get Mr. Stanford all the men he requires, and will help him in pushing forward with his work. It is a wonderful thing telegraphy. I am in the dark. I cannot understand it." The company is now laying the wire from Ramoutsa to Meschudi Lindewe's Town, which is to be the next station.

**Personal.**—Mr. Mark Bevan has commenced business at Cardiff as an electrical engineer and contractor. Mr. Bevan was, for several years, superintendent at Rio-de-Janeiro, for the Western and Brazilian Telegraph Company, and for 4½ years was in the service of Messrs. Siemens Brothers and Company at their works at Woolwich. On the recommendation of Messrs. Siemens Brothers he afterwards held the appointment of chief electrical engineer in the Torpedo Division of the Argentine Navy, and a similar appointment under the Chilean Government.

**Intended Electric Light on Borkum Island.**—The German Government has given notice that, during the summer of 1890, an electric light will be placed on Borkum Island, east side of River Ems entrance, about 1,200 yards southward of the principal lighthouse. It will be elevated 105 feet above high water, and should be visible in clear weather from a distance of 16 miles. During the summer of 1890, an electric light will be also placed near Campen, about four miles northward of Knock Lighthouse, east side of River Ems.

**The Houses of Parliament Lightning Rods.**—Messrs. R. Anderson & Co., the firm responsible for the lightning conductors on the Houses of Parliament, write respecting the recent fall of a piece of masonry, when Mr. Justice Grantham narrowly escaped. They state that examination has proved that the piece of stone had been cracked for some time before, and that the building was in no way damaged by lightning.

**Austin's Infant Dynamos.**—Mr. Austin informs us that he has secured Messrs. Paterson and Cooper as London agents for the sale of his dynamos and motors.

### NEW COMPANIES REGISTERED.

**Electricity Supply Companies Union, Limited.**—Capital, £100 in £1 shares. Objects: To form centres at which electrical energy may be generated and accumulated, and from which the same may be distributed for public and private lighting, for motive power or heat, for electro-plating, electro-deposition, telephonic, or other purposes. Signatories (with 1 share each): J. D. Pearson, 3, Oakleigh Road, New Southgate; W. A. Pittman, 7, St. Helen's Gardens, North Kensington; J. Aspinall, 34, Bowman's Buildings, Edgware Road; Wm. May and A. W. Bartlett, 18, Austin Friars; J. B. Rands, 5, Linnell Road, Camberwell; G. W. Schofield, 27, Austin Friars. Registered without special articles by Slaughter and May, 18, Austin Friars.

**Amalgamated Electricity Supply Companies, Limited.**—Capital, £100 in £5 shares. Objects and signatories as in preceding company. Registered 16th inst. by Slaughter and May, 18, Austin Friars.

**United Electricity Supply Companies, Limited.**—Capital, £100 in £5 shares. The objects and signatories are the same as in the two preceding companies. Registered 16th inst. by Slaughter and May, 18, Austin Friars.

**Woodward, Grosvenor and Company, Limited.**—Capital, £90,000 in £10 shares. Objects: To take over the businesses of Woodward, Grosvenor & Co., and the Stour Vale Mill Company, carried on at Kidderminster and 102, Newgate Street, and to trade as carpet manufacturers, spinners, general merchants, engineers, electricians, soap and glue manufacturers, &c. Signatories (with 1 share each): \*G. W. Grosvenor, Broome House, near Stourbridge; \*H. Mountford, Thurlow Park Road, West Dulwich; J. Mountford, M. Waite and R. Moule, Kidderminster; J. Lignton, Streatham Park; H. C. W. Mountford, West Dulwich. The first two signatories are appointed managing directors, each at a salary of £1,000 per annum. The company in general meeting will determine remuneration of ordinary directors. Registered 18th inst. by Emmett, Sons and Stubbs, 14, Bloomsbury Square.

**Franco-African Lighting Syndicate, Limited.**—Capital, £25,000 in £1 shares. Objects: To carry on in Algeria, Tunis, or other part of the French Dominions or Protectorates, the business of a gas or electric light company in all branches. Signatories (with 1 share each): E. G. Inman, 269, City Road; W. Cousens, 17, Victoria Street, S.W.; G. A. Stanbrough, 8, Hetherington Road, Clapham; T. W. Gardiner, 6, Heiron Street, S.E.; F. Burbidge, 44, Amwell Street, E.C.; E. Boucher, 229, High Street, Lewisham; E. G. Tanton, 11, Queen Victoria Street. Directors remuneration, £50 per annum each, and in addition 10 per cent. per annum on the net profits, the chairman to be entitled to double fees. Registered 19th inst. by Wm. Cousens, 17, Victoria Street, S.W.

**Earthy Metals Company, Limited.**—Capital £2,000 in £50 shares. Objects: To carry out an unregistered agreement with Luis Falero, M.F.S.T.E. To produce and prepare for market, sodium, potassium, magnesium, aluminium and other metals, and to carry on business as metallurgists, manufacturing chemists, and of makers of and dealers in electrical, chemical and scientific apparatus and materials. Signatories (with

1 share each): Major J. G. Scott, Winkfield, Berks; A. Codogan, 3, Sloane Gardens, S.W.; J. M. Maclean, M.P., 40, Nevera Square; J. W. Macfarlane, 2, Lexham Gardens; R. St. John Boddington, 15½, Parliament Street; H. M. Cadell, Bournemouth, N.B. Registered 19th inst., without special articles, by E. R. Crump, Solicitor, 15½, Parliament Street.

### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Windsor and Eton Electric Light Company, Limited.**—The registered office of this company is situated at 54, High Street, Windsor.

**Corinthian Electric Medical Battery Company, Limited.**—The annual return of this company, made up to the 30th June, was filed on the 15th inst. The nominal capital is £25,000 in £1 shares. 20,804 shares have been taken up, 20,000 of these being considered fully paid. Upon 804 shares the full amount has been called, the calls paid amounting to £800, and unpaid to £4. Registered office, 1, Gate Street, Lincoln's-Inn-Fields.

**Siemens Brothers & Co., Limited.**—The annual return of this company, made up to the 15th inst., was filed on the same day. The nominal capital is £500,000 in £100 shares, the whole of which are taken up. The sum of £85 has been called and paid upon each share, the paid up capital thus being £425,000.

**Mining and General Electric Lamp Company, Limited.**—The annual return of this company, made up to the 17th inst., was filed on the 19th instant. The nominal capital is £100,000 in £1 shares, 90,000 of which are taken up, 62,305 being considered fully paid. The full amount has been called and paid upon 27,695 shares.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### The United River Plate Telephone Co., Limited.

In the absence of Lord Thurlow, Mr. J. Irving Courtenay, the deputy chairman, presided at the fourth annual ordinary general meeting of the shareholders, held at Winchester House on Tuesday last, to receive the report (printed in our last issue) and accounts for the year ending March 31st, 1890. About half a dozen shareholders were present.

The Chairman said the financial position in Buenos Ayres could not but be a cause of anxiety to all who were interested in the Argentine Republic. But from the best obtainable information—and the company was fortunate in numbering amongst its directors gentlemen who had passed the greater part of their lives in the River Plate—he believed that, with a prudent administration of its affairs, the country, with the aid of its great resources, would speedily overcome its present difficulties. The company's gross income for the year ending March 31st, 1890, amounted to £108,612 2s. 7d., as against £81,866 2s. 4d. for the previous twelve months. Those figures showed how largely the business had developed during the past year. There had been a considerable increase in working expenses, which was mainly caused by a large increase in wages and cost of material. Fortunately, there had been no serious question with the *employés*, but, as in the case of other River Plate companies, the depreciated currency had made the increase inevitable. There had also been some increase in taxation. These had caused an increase in the working expenses. A special item of expenditure was owing to the repairs rendered necessary by a cyclone in Rosario last December. The gravest loss, however, and that which was the cause of their reduced dividend, was that on exchange. It was one beyond the directors' control. It amounted to not less than £22,334 17s. 1d., as against £14,689 6s. 8d. in the previous year, or an increased loss of £7,645 10s. 5d. The total loss from this source was, therefore, about 8 per cent. on the company's paid-up capital. The result, after paying working expenses, debenture interest, and general charges, both in the River Plate and in London, was a profit of £34,198 6s. 5d., from which, after deducting the loss on exchange, viz., £22,334 17s. 1d., there remained a net profit of £11,863 9s. 4d., which, added to the balance from last year, viz., £1,210 7s. 2d., amounted to £1,373 16s. 6d. An interim dividend of 2 per cent., or £5,800, was paid in January last, and the directors recommended a further payment of 1 per cent. out of the balance. They proposed to carry forward £2,000 to the depreciation and renewal account, which would then stand at £9,000.

and they carried forward a balance of £2,373 16s. 6d. In view of the abnormal state of business in the Republic (which had continued for some time) the results obtained were fairly satisfactory, and he trusted the policy of the directors in carrying forward a substantial sum would be approved. There were some encouraging features in connection with their business in the Plate. On the 31st March, 1890, the date of the balance sheet, the number of their subscribers at Buenos Ayres was over 5,000. The company began business with about 3,000 subscribers. As might have been expected during such a crisis, a considerable number of people had taken out their telephones; but, on the other hand, each month had seen a steady influx of new subscribers, and, all things considered, the business of the company showed a most remarkable vitality. That was mainly owing to careful and vigilant administration both in Buenos Ayres and in Rosario. One of the company's representatives in Buenos Ayres wrote:—"We are giving a service such as we can safely say has never been given in Buenos Ayres before. Of course we have complaints, but they are brought down, we think, to a minimum and neutralised by the many expressions of satisfaction we hear on all sides." The shareholders would congratulate themselves upon having such painstaking and zealous representatives as Mr. Fells and Mr. Crabbe at Buenos Ayres and Mr. Chapple at Rosario. The directors had successfully carried out what was hinted in last year's report—i. e., they had raised the rates of subscription with a view to meet to some extent the increased expenditure and exceptional charges incident to the condition of currency in the Plate. The capital outlay for 1889-90 was £7,297 14s. 11d. less than in 1880-89, and that allowing for the outlay during that period for the purchase of the Rosario business. They had not lost sight of the construction of the Rosario trunk line, to be undertaken when a favourable opportunity presented itself. The issue of the 5 per cent. debenture stock and the conversion of 7 per cent. debentures had been satisfactorily carried out, and had evidently been appreciated by the shareholders. He was confident of the company's future. It was plain the business was steadily improving, and they might therefore expect at the end of the crisis to reap the fruits of the solid progress and the improved position they had attained in spite of the serious increase of financial obstacles they had and still encountered. Their receipts for the first quarter of the new year—that is, April to June—had exceeded those of any other quarter since the company started business. He moved the adoption of the report and accounts, and to declare a dividend of 1 per cent., or 1s. per share free of income tax (in addition to the interim dividend of 2 per cent. paid in January last), payable out of the remaining balance of £7,273 16s. 6d.—viz., £22,900.

Mr. Frank Jones seconded.

Mr. Peel, a shareholder, congratulated the directors upon the present position of the company. He, however, thought they might have imitated other companies and maintained its dividend. But that was a question of finance, and the directors might have acted discreetly under the circumstances.

Dr. Ellis asked whether the large increase of business was caused by the taking over by his company of the Rosario business. He also observed that last year the company paid 6 per cent. dividend, and had the rate of exchange remained the same, the company would be paying only 5 per cent. in the present year—that was to say, a difference of £7,000 in exchange would have meant 2 per cent. more than they actually received. He further said that the expenses caused by cyclones and that kind of thing ought to be met out of the depreciation and renewal fund. He also asked what had been the rate per cent. of the increase in subscribers from the 1st of January last. He felt sure the directors had done their very best, and that the feeling was shared by the other shareholders was manifest by the smallness of the meeting.

The Chairman replied that while it was true that the Rosario business had been taken into account, apart from that there had been a considerable increase in the Buenos Ayres business. He did not think it advisable to give precise figures of the increase in new subscribers. The increase in the rates of subscription had by no means had the prejudicial effect which some persons anticipated. In circumstances like depreciation of currency there was always increase in the cost of material, and that had seriously told upon the company. While he promised to take note of the observation with regard to charging damage from cyclones to the depreciation and renewal account, he thought they ought to have a strong reserve. This was essentially a time for a cautious policy.

Lord Thurlow and Mr. Fredk. Green were re-elected directors, Messrs. Cooper Bros. & Co. were reappointed auditors, and, with a vote of thanks to the board, the proceedings terminated.

### Crompton and Company, Limited.

THE second annual general meeting of the shareholders was held at the Cannon Street Hotel, on the 21st inst., when the report for the year ending 31st March, 1890 (printed in our last issue), with the accounts, was laid before the meeting.

The Chairman, Mr. R. E. B. Crompton, briefly alluded to the loss the company sustained by the death of Viscount Torrington. That loss was extreme. The deceased had taken an exceedingly keen interest in the company's affairs. When they last met some 1,200 of the preference shares had not yet been placed, but were allotted immediately afterwards. The directors then, in accordance with the terms of the prospectus,

applied to the Stock Exchange for a settlement and quotation for the preference shares. These had since been accorded. There had not been many sales in the past year, the apparent explanation being that members did not wish to part with what they believed to be a good dividend paying property. The company's business had increased very largely, and the directors had consequently been compelled to add to the plant at Chelmsford and elsewhere, and to increase the working capital, to do which they had exercised their borrowing powers, and had issued 5 per cent. debentures to the amount of £50,000, which was secured by a deed of mortgage. The whole of the £25,000 of debentures, originally offered, had been applied for, and the directors now proposed to offer the remaining £25,000 for subscription, and a circular would be sent out accordingly. The sum of £6,750, which last year appeared on the balance-sheet as a loan on mortgage of the Chelmsford works, had been paid off, and the debenture debt remained the only charge on the property. The profit for the year was £10,610 1s. 7d., or £2,000 more than the year before, and about £4,000 more than the average of the six years which preceded the formation of the company; a result which might be considered fairly satisfactory. After payment of the interim dividend in December last year, and providing for debenture interest and other charges, and after carrying the sum of £500 to the doubtful debts and contingencies account, there remained a balance of £6,030 6s. available for dividend, and out of this the directors proposed to pay 7 per cent. per annum for the half-year to the preference shareholders, and 5 per cent. upon the ordinary shares, carrying the balance, £474 18s. 10d., forward to the next year. The company's increasing business had necessitated capital expenditure for extension of premises and additions to plant. They had also taken over the portion of the company's Chelmsford property, which was leased to Crompton and Fawkes, and which adjoined the Arc works, and these were immediately available for the extension of the Arc works. During the past year the company had the good fortune to secure very large orders from three most important supply companies—viz., the Westminster, the Kensington, and the Notting Hill, for the fixing of machinery, and the supply and fixing of a complete system of underground mains, extending 40 or 50 miles through the London streets. In the early part of the year they worked with a separate staff taken from the temporary premises of the company's Kensington Court estate. These temporary premises, being no longer available, the directors had thought it advisable to lease the convenient premises, No. 1, Lillie Road, West Brompton, which were being fitted up, and were now the head-quarters of the company's engineering staff in connection with those large West End orders. The principal feature of those orders was that they seemed to offer a fair chance of a good profit, while the risks were not great. As regards other prospects, the company's order books were full for its own special type of large dynamo machines, switchboards, and that class of plant, and the general prospects of orders were better than he, the speaker, had ever known them to be since he entered the electrical business. They might congratulate themselves on the extremely good feeling prevailing between the staff and the workmen. They had succeeded in organising piecework on a more considerable scale than had yet been attempted, without encountering the difficulties which other engineering firms had met with. That was a great deal due to the tact and good management of the Chelmsford managers. The very delicate question of piecework had been the bone of contention which had caused so many strikes all over the country. In the company's case it was a great step in advance, as it enabled it to keep accounts and to know the cost of its work with much greater accuracy than was possible when the bulk of the work was done by day labour. Regarding the accounts, they called for no special remark from him. He therefore moved the adoption of the report and accounts.

The Secretary, in reply to a shareholder, explained that the accounts of the Australian Company were not yet to hand; one of the managers of that company was bringing them over. In the meanwhile they were said to show a very satisfactory profit. The motion was seconded and carried unanimously.

The Chairman moved to declare a dividend at the rate of 7 per cent. per annum for the half year, payable on the company's preference shares, and a further dividend of 5 per cent. per annum upon the ordinary shares. The motions were seconded and carried unanimously.

The Chairman, in moving the re-election of Sir Charles Grant, K.C.S.I., as a director, spoke in warm terms of the services of that gentleman, who became chairman of the company on the death of Lord Torrington. If he, Mr. Crompton, occupied that position to-day, it was because from his intimate connection with the business, he was the best fitted to answer questions. But Sir Charles Grant had been a very powerful and steadfast member of the board, and one whose loss, if he left it, would be greatly felt. The motion was seconded and carried unanimously.

The Chairman, replying to a vote of thanks to the board, said the sole business of his life was to look after the company's interests. The proceedings then terminated.

### The South of England Telephone Company, Limited.

THE seventh ordinary general meeting of the shareholders was held at Winchester House, on the 18th inst., at twelve, when the following report for the year ending 30th April, with a statement of accounts, was presented. The expenditure on capital account for the past year amounts to £14,116 2s. 10d., bringing the total of that account to £78,418 2s. The revenue account shows a sum

of £21,549 18s. 9d. for subscriptions and rentals, and a net credit balance of £6,148 5s. 4d., making, with the sum of £627 1s. 2d. brought forward from last year, an available balance of £6,775 6s. 6d. Of this amount the sum of £1,796 14s. 7d. has been absorbed by the payment of an interim dividend on the preference shares at the rate of 6 per cent. per annum for the half-year ending 30th October, 1889. In order to strengthen the position of the company, the directors have considered it advisable to carry £1,000 to the reserve fund; and they now recommend the payment of a final dividend at the rate of 6 per cent. on the preference shares (£2,096 6s. 2d.), for the half-year ending 30th April, 1890, and the payment of a dividend of  $\frac{1}{2}$  per cent. on the ordinary shares, free of income tax (£1,500), for the year, leaving a balance of £382 5s. 9d. to be carried forward. The completed trunk lines are as follows:—Brighton—Shoreham; Brighton—Eastbourne; Brighton—Worthing; Shoreham—Worthing; Brighton—Hurst; Brighton—Newhaven; Brighton—Rottingdean; Brighton—Lewes; Lewes—Eastbourne; Canterbury—Ramsgate; Ramsgate—Margate; Ramsgate—Sandwich; Ramsgate—Deal; Canterbury—Faversham; Canterbury—Whitstable; Canterbury—Dover; Dover—Folkestone; Chatham—Maidstone; Norwich—Great Yarmouth; Northampton—Wellingboro'; Wellingboro'—Kettering; Kettering—Rushden; Tunbridge Wells—Tonbridge.

The trunk lines in course of construction are Canterbury—Ashford; Faversham—Sittingbourne.

At the 30th April this year, 2,265 exchange lines and 583 private lines were completed, and 91 exchange lines and 19 private lines were in course of construction.

Telephone exchanges are now open at the following places:—Brighton, Cambridge, Canterbury, Chatham, Deal, Dover, Eastbourne, Faversham, Folkestone, Great Yarmouth, Hastings and St. Leonards, Hurst, Hythe, Ipswich, Kettering, King's Lynn, Lewes, Maidstone, Margate, Newhaven, Northampton, Norwich, Oxford, Peterborough, Ramsgate, Reading, Rottingdean, Rushden, Sandgate, Sandwich, Shoreham, Tunbridge Wells, Watford, Wellingborough, Whitstable, Worthing.

#### Comparative Statement of Exchange and Private Line Business.

	Exchange.	Private.
April 30th, 1886 ... ..	687	248
April 30th, 1887 ... ..	1,130	348
April 30th, 1888 ... ..	1,521	386
April 30th, 1889 ... ..	1,972	500
April 30th, 1890 ... ..	2,356	602

The Chairman (Mr. D. O. Bateson), explained why the report and balance sheet had been delayed. The company's licence from the Post Office was terminable at periods of seven years by six months' notice from the Postmaster-General; and that notice not having been given, the company had a fresh life of seven years. It was thought undesirable that the state of the company's affairs should be published so long as the matter of the licence was uncertain; but after the Postmaster's decision was known no time was lost in presenting a report and calling a meeting. The company's books were, in fact, balanced and its accounts ready for audit six months before the 30th April. The reason why the preference dividend was not paid at the beginning of May, as formerly, was that some of the shareholders doubted the correctness of the former practice. They said that while it was perfectly right to pay an interim dividend on the estimate of profits, it was scarcely business-like to make the final distribution before ascertaining the correct balance. The directors had adopted that view, and propose to continue it in practice. There was no reason to complain of the progress of the company's business. The increase was not very rapid, but it was continuous and steady, considering the somewhat bad pasture. He was sorry the National Telephone Company apparently could not see its way to admitting the company to its system, as the company was thereby debarred from exploiting the most valuable part of its district, namely, that within the 20 miles radius of London. There were many residents and business firms most anxious for this means of communication, which, he thought, could not long be delayed, as it would be extremely profitable to the telephone companies. The trunk line system in East Kent would shortly be completed by the opening of a route between Ashford and Canterbury, which would place the former town in communication with nearly all the business centres and seaside towns in the district. They were indebted to Lord Winchelsea for the grant of wayleaves through Eastwell Park. The cost of wayleaves was increasing, and though, as a rule, they were granted without much difficulty, the directors had occasionally to complain of being squeezed unmercifully. In such cases they preferred to alter the route, if possible, even at considerable extra expense. The rating question was becoming serious for telephone companies, and the question had been raised in many places. In Brighton, the board appealed to the Quarter Sessions against a heavy assessment in vain, and as the parent company would be no party to the expense of an appeal to the Queen's Bench, it had to be relinquished. As regards the accounts, the gross rentals had increased by £3,676; that was about the usual average. This year, however, the shareholders derived no benefit from the improvement, as the auditors stood out for carrying a much larger proportion of the wages and office expenses to revenue than was thought necessary last year. The reserve, it was thought, ought to be increased, as it had not been altered for some years; and, no doubt, the older the company grew, the expenditure necessary for repairs of lines, altering routes, &c., grew also. That, however, the directors provided for in the

balance sheet originally submitted; but the shareholders' auditor was resolved that the entire increase for the year should go for maintenance, although the working of the new lines was undoubtedly capital expenditure. The directors still thought so large a sum as £3,758 an unnecessary and inequitable addition to the maintenance fund, but as a clean certificate was refused, and they were threatened with a contentious meeting, they agreed to the inevitable, and left the matter to the shareholders. No doubt the alteration would strengthen the financial position of the company, and though probably the selling value of the ordinary shares would be temporarily lessened to a small extent, the value of the preference shares ought at least to be maintained, as they were a steady and reliable security. He moved the adoption of the report and accounts, and to declare a dividend at the rate of 6 per cent. per annum for the half-year ending April 30th, 1890, on the preference shares, payable the 19th inst., and a further dividend at the rate of  $\frac{1}{2}$  per cent. per annum, free of income tax on the ordinary shares, payable on the 19th.

The resolution was seconded by Mr. C. Billett, who, whilst regretting last year's 1 per cent., reminded them that the missing  $\frac{1}{2}$  per cent. would go to strengthen the company.

The motion was carried unanimously.

The Chairman, replying to a shareholder, as to negotiations between the company and the National Telephone Company, said that no such negotiations had ever taken place. The directors could do nothing without the shareholders' consent at a general meeting.

A shareholder strongly objected to anything like the company's shares being valued at 5s., as the National Telephone Company appeared to do by their report.

Mr. Bateson was re-elected to the Board, and Mr. J. Weise, the shareholders' auditor, was re-appointed.

With a vote of thanks to the Board, the meeting closed.

#### The Direct United States Cable Company, Limited.

THE report of the directors for the six months ended 30th June, 1890, to be presented at the twenty-sixth ordinary general meeting of the company, to be held at Winchester House, 50, Old Broad Street, in the City of London, on Friday, the 25th day of July, 1890, at 2 p.m., states:—The half-year's revenue (subject to revision on decision of the case mentioned below), after deducting out-payments, amounted to £40,017 1s. against £39,626 8s. 5d. (after similar deductions) for the corresponding period of 1889, being a difference of £390 12s. 7d. in favour of the half-year under review.

The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cables, amounted to £17,616 5s. 8d., leaving a balance of £22,400 15s. 4d. as the net profit of the half-year, making, with £8,317 19s. 4d. brought forward from the previous half-year, a total of £30,718 14s. 8d. For the corresponding half-year of 1889 the working expenses and other payments amounted to £16,676 3s. 9d.

Three quarterly interim dividends of 3s. 6d. each per share, amounting to £31,872 15s., have been declared and paid during the financial year, and a final payment of 3s. 6d. per share is now proposed, making, with the three interim dividends, 3 $\frac{1}{2}$  per cent. for the year, being a total distribution of £42,497. An amount of £8,502 4s. 5d. has been transferred to the reserve fund account, which now stands at £250,000, and the balance of £968 0s. 3d. on the revenue account is proposed to be carried forward.

During the earlier portion of the past half-year the traffic showed a slight diminution as compared with the corresponding period of the previous year, but lately an increase has taken place which it is hoped may be progressive.

The Anglo-American Company having in January last opened offices of its own in New York, the expense of the office at 40, Broadway, in that city, previously maintained as a joint office, is now entirely borne by this company, accounting for the increase in the expenses during the past half-year. The maintenance of an independent office in New York is regarded as necessary.

A station has been opened by this company at 40, Hope Street, Glasgow. These additional facilities are already producing beneficial results.

A break occurred in the short section of cable on January 19th last, about 122 knots from Halifax, which was repaired on March 30th.

On April 10th a fault was removed from the shore end of the same cable near Rye Beach.

On May 26th a break occurred in the main cable which was promptly repaired on the 29th.

The breaks in the cables were found to have been caused by vessels' anchors.

The repairing operations have cost £4,919 13s. 5d., which has been debited to the reserve fund account as heretofore.

The interests of the company were represented at the International Telegraphic Conference recently held in Paris. In the case of the Anglo-American Telegraph Company v. Cie. Française du Télégraphe de Paris à New York, the appeal to the Council of State, mentioned in the report to the 30th June, 1889, is still pending. Pursuant to the provisions of the Articles of Association, two of the directors, viz., Charles Meara, Esq., and E. M. Underdown, Esq., Q.C., retire by rotation, and being eligible, offer themselves for re-election.

Mr. John G. Griffiths, F.C.A., and Mr. John Sawyer, F.C.A., the auditors, retire pursuant to the Articles of Association, and offer themselves for re-election.

**The Westinghouse Electric Company.**

At a meeting of the stockholders of the Westinghouse Electric Company on July 8th, at the offices of the company in the Westinghouse Building, Pittsburgh, Pa., Mr. George Westinghouse, jun., made a statement to the meeting, in which the following occurs:—The board of directors are of opinion that a total increase in the capital stock of not less than \$5,000,000 should now be authorised in order to provide for the future requirements of the company. It is proposed to issue forthwith to each stockholder of record on this date an assignable right to subscribe, on or before August 1st, 1890, for one half share of stock for each share now standing in his name on the books of the company, at \$40 per share, this price being determined by a distribution or an allowance from the surplus earnings. Of this price one-quarter will be payable on August 1st, one-quarter September 1st, one-quarter October 1st, and one-quarter November 1st. Mr. Geo. Westinghouse, jun., has agreed to take \$1,250,000 of stock on the terms above indicated. If each of the other stockholders will subscribe to the number of shares to which he is entitled, the company will be enabled to provide for a large increase in its business. The board believe it to be to the pecuniary interest of each stockholder to subscribe for his amount of stock, and thereby aid in increasing the earning capacity of the company, which will have the immediate effect of enhancing the value of the shares already outstanding, and of the shares which in this manner will be secured at a reduced rate. The board believed that great profit would accrue to the company by securing foreign patents on the more important of the inventions exploited by it in this country. This policy resulted in an order from the Metropolitan Electric Supply Company, Limited, of London, for a central station of 10,000 lights capacity, which has since been increased to 25,000. The station is now in operation with entire satisfaction, and is the most complete and perfect central station in Europe. A company known as the Westinghouse Electric Company, Limited, has been organised in London, to operate these patents, and this company has received in payment for the patents and the money expended in the development of that business £301,000 of the stock of that company, which is the controlling interest. The English company has recently received orders for other plants, and is in negotiations for others of a very extensive character, with every prospect of success. Indeed, the business abroad bids fair to reach proportions that will equal, if not be greater, than those of the parent company, and to be a source of great profit to it. The majority of the board of the Westinghouse Electric Company, Limited, are also members of the Westinghouse Brake Company, Limited, of London, and the business is being conducted on the same lines which rendered the latter company so successful. Its operations are under the supervision and direction of Mr. H. M. Byllesby, the vice president of this company, who is its managing director, and is now in England giving it his personal attention.

**The Mutual Telephone Company, Limited.**

A MEETING of the shareholders of the Mutual Telephone Company Limited, was held on Monday in the Memorial Hall, Albert Square, Mr. A. D. Provand, M.P., in the chair.

Mr. Provand said the first resolution was that the capital of the company be increased to £350,000. The company was registered with £100,000 capital, which was sufficient for Manchester and Liverpool, but they had had so much encouragement in Glasgow—where more than 1,000 firms have signed the preliminary circulars—and also in other places, that they now asked for the capital to be increased sufficiently to allow them to commence operations in other cities. None of this capital was to be asked for in Manchester. They required £45,000 to erect their exchange; more than £40,000 of this had been allotted, and applications were steadily coming in. They had therefore all that was required for Manchester. The second resolution to alter the articles of association, so as to permit them to pay interest up to 10 per cent., instead of being limited to 6 per cent. This alteration was asked for because they had found it difficult to create a company on strictly mutual terms—that was to say, every renter of the company's telephones being a holder of shares in the company. As all the renters were not shareholders, some of them must take an increased number of shares to make up for those who took none, and it appeared 6 per cent. was not a sufficient inducement for these shares to be taken up, nor was it a sufficiently high rate of interest to promise to pay on the business. This would not add much to the working expenses. In their estimate of earnings they put down the 2,500 wires of the Manchester exchange at £5 each, which was the rate to shareholders, but probably 1,500 or 1,600 of their wires would be rented by non-shareholders, who would pay the higher rate of £6. This would add, say, £1,500 or £1,600 to their earnings, and if they paid the full 10 per cent. interest on the 4,500 shares held in Manchester, it would amount to only £1,800 extra interest, which would be almost met by the extra rates for the telephones rented by non-shareholders. They had in Manchester about 650 shareholders, and when all their wires were applied for, they expected the number would be 900, perhaps even 1,000, holding 4,500 shares; and as the strength of the company largely depended on the number of shareholders, everything should be done to increase that number. The resolutions were put to the meeting and carried.

**The Edison and Swan United Electric Light Company.**

THE directors' report and the accounts for the year ending 30th June, 1890, states the business of the company has resulted in a credit balance of £61,115 3s. 3d. Of this amount £12,371 14s. 7d. has been absorbed by the payment of an interim dividend on the A shares, at the rate of 7 per cent. per annum, for the first six months of the year. The directors recommend the payment of the following dividends on the A shares, free of income tax, and to be distributed in accordance with Clause 87 of the Articles of Association:—

(a.) At the rate of 7 per cent. per annum for the half-year ending 30th June, 1890 (making 7 per cent. for the year):

(b.) Four per cent. in completion of payment of arrears of cumulative preference dividend for the year ending 30th June, June, 1884:

(c.) Four per cent. in respect of arrears of cumulative preference dividend for the year ending 30th June, 1885:

which will absorb £40,649 19s. 3d.; leaving £8,093 9s. 5d., which the directors have carried to the reserve fund, in accordance with Article 89 of Articles of Association. The directors have been adding to the buildings and plant at the factory so as to enable them to manufacture lamps in sufficient numbers to meet the demand which will arise as the supply companies extend their operations in London and other towns. Mr. Shelford Bidwell, F.R.S., retires from the board, and offers himself for re-election as a director. The auditors, Messrs. Welton, Jones and Co. retire, and are eligible for re-election.

**The Manchester Edison-Swan Company, Limited.**

In their report for the year ending May 31st, 1890, to be submitted with the accompanying balance-sheet at the meeting of shareholders on the 28th inst., at the Albert Memorial Hall, Manchester, the directors state the net profit, including last year's balance, as £1,647 6s., which they propose to appropriate as follows:—£1,000 to payment of dividend at 5 per cent per annum, and £647 6s. to balance carried forward. It is proposed to issue the dividend warrants on August 1st, 1890. Mr. W. P. James Fawcus has been appointed managing director, vice Mr. J. R. Williams resigned through ill-health. The retiring directors, Sir Jos. C. Lee and Mr. J. C. Waterhouse, offer themselves for re-election.

**The Wendigo Copper Company, Limited.**—This company was advertised this week with a capital of £225,000. Of this a first issue of 12,500 shares of £5 each is offered to the public, and a like number of shares will be taken by the vendors in part payment of purchase money. The object of the company is to purchase a large tract of land situate on Isle Royale, Lake Superior, Michigan, U.S.A., amounting in all to about 5,120 acres, and to prosecute mining and the development of its mineral and other resources, which are said to be extensive. The copper is in its pure metallic state, and is termed "native," and the methods of winning it and reducing it to cake and ingot copper are the simplest and cheapest. As the company will have its own harbour and docks on the property, the cost of the transit should be less than from many of the mines on the south shore.

**The Eastern Extension Australasia and China Telegraph Company, Limited.**—The directors notify that the coupons on this company's 6 per cent. debentures, due on August 1st proximo, will be paid on and after that date at the Consolidated Bank, 52, Threadneedle Street, E.C. Coupons must be left three clear days for examination.

**The Cuba Submarine Telegraph Company, Limited.**—After placing £2,500 to the reserve fund, the directors recommend a dividend at the rate of 8 per cent. per annum for the half-year ended June 30th, leaving £501 to be carried forward.

**Anglo-American Telegraph, Limited.**—Interim dividend for the quarter: 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, payable on 1st August.

**The Eastern Extension Telegraph Company.**—It was notified early in the week that telegraphic communication with Australia, New Zealand, and Tasmania is now restored.

**The Chemical Carbon Company, Limited.**—It has been resolved to wind up the company, Messrs. A. Dowling and Thos. Purberry, of Basingstoke, to be liquidators.

**Elmore's Patent Copper Depositing Company, Limited.**—The transfer books will be closed till July 28th, inclusive, for the purpose of paying a dividend.

**TRAFFIC RECEIPTS**

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending July 18th, amounted to £4,174.

West India and Panama Telegraph Company, Limited. The estimated traffic receipts for the half month ended the 15th July, are £2,879, as compared with £2,553 in the corresponding period of 1889.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending July 18th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,208.

REPORT ON THE LINEFF ELECTRIC  
TRAMWAY SYSTEM.

I HAVE examined and tested the new Lineff Electric Tramway system, with underground conductor, at the dépôt of the West Metropolitan Tramway Company, at Chiswick.

The main feature of the new Lineff system is the employment of a conductor placed in a conduit or channel closed on all sides, so that no slot or other opening in the road is required for establishing electrical communication between the generating dynamos at the power station, and the propelling motor on the car. This communication is established by means of short pieces of insulated rail, laid between and parallel with the ordinary tram rails, and a continuous conductor placed below the insulated rails, in a channel or conduit formed of insulating materials. The conductor consists of naked copper strip or cables upon which is laid a strip of galvanised iron. There is a small interval between the upper surface of the iron strip and the lower surface of the insulated or third rail, and the latter is not in electrical communication with the power station as long as this interval is maintained. This is the case on all portions of the line not occupied by cars, and therefore the third rail may, where accessible, be walked upon or touched without the slightest danger from electrical shocks. Immediately under the car, however, two or three sections of the third rail are in contact with the buried conductor, and become thus charged to the potential of the latter. This contact is produced by magnetic action, which draws the iron strip up, and presses it against the lower flange of the short pieces of insulated rail, which thus become part of the conductor, from which the current is picked up by contact wheels and led to the motor on the car. The return circuit is, as usual, through the rails and earth. As the car travels along, the underground iron strip is dropped behind and picked up in front, thus maintaining continuity of connection with the power station over its whole journey, whilst, at the same time, leaving the track in front and rear of the car perfectly free from electrical charges. The magnetic action between the insulated rails and underground conductor is produced by an electro-magnet carried under the car. This electro-magnet is ordinarily energised by a current obtained from the conductor, but it can also be energised by a current obtained from one storage cell, so that the conductor, should it accidentally have been dropped, may be picked up at any point on the line.

The car employed was an open summer car, carrying 20 passengers, besides driver and conductor. I estimate the weight of car, as fitted with a 4 H.P. motor, chain gear, magnetic brake and other accessories, at 35 cwt., without passengers.

The object I had in view when making the tests, of which I give a detailed account in the appendix to this report, was to ascertain whether the Lineff system in its present form is likely to prove successful in practical work. The answer to this question depends mainly upon three considerations, viz., safety to the public, efficiency of service, and economy of working. I deal with these considerations separately.

## SAFETY TO THE PUBLIC.

The car, when running at full speed, can be stopped within a distance of 9 feet, or less than its own length. This power of control is amply sufficient for practical purposes. There remains the further question, whether there is any danger of persons or animals receiving shocks from stepping upon the insulated rails in front or behind the car.

The length of an ordinary car is 21 feet, so that the nearest accessible point of the insulated rail is about 11 feet from the centre of the car. My experiments lead me to conclude that the charged region of the insulated rail can, at all speeds, be restricted to within about 9 feet in advance and behind the centre of the car, leaving 2 feet of rail under the car at either end, and all the rail beyond the ends free from electrical charge, so that there is no danger of persons or animals receiving shocks from the rail.

The collection of current from the magnetic rail is so arranged as to avoid sparking.

## EFFICIENCY OF SERVICE.

I found the magnetic picking-up gear perfectly reliable, both on the straight single line and on a branch or crossing. I have already mentioned that as a further precaution against losing the current each car will be equipped with a storage cell for picking up, and there will thus be no danger of a car losing its propelling power and blocking the road.

## ECONOMY OF WORKING.

Compared with a car worked by an overhead line, the present Lineff car will require from  $\frac{1}{3}$  to  $\frac{2}{3}$  of a horse-power more, but as electric tramways on the overhead wire system are inadmissible for urban and suburban traffic, the comparison must be made either with an underground slot system or with cars propelled by storage batteries. As regards the former, there is no perceptible difference in power between it and the closed magnetic channel system. With storage cars, the power required is however considerably in excess of that required with the closed magnetic channel, for the simple reason that, in addition to weight of car, motor, and passengers, the weight of the storage cells must also be taken into account. With the Lineff system  $7\frac{1}{2}$  horse-power will be required to propel a full-sized car at 7 miles per hour. To propel the same car by storage batteries would require carrying an additional weight of 3 to 4 tons, and an expenditure of about 12

horse-power. Making due allowance for the loss of power in charging and discharging the storage cells, I find that the total amount of steam power required at the station would, with storage cars, be about double that required by the Lineff system.

## NOVELTY.

With regard to the novelty of the Lineff magnetic conductor, I may add that although magnetic action has been used before by several inventors for actuating switches which establish electrical contact between a sealed main and separated lengths of surface rails, yet the idea of a continuous magnetic conductor forming, so to say, one single switch for the whole line, is entirely novel and strikingly simple. The arrangement of magnetic rails on the hit and miss principle is also entirely new, and secures a great economy in the energy necessary to effect the attraction of the continuous magnetic conductor.

This part of the invention especially has been worked out with great skill and care, as is amply testified by the good results obtained under the very unfavourable conditions imposed by the necessities of road traffic and by other mechanical considerations. The fact of having one set of magnetic rails only exposed on the surface, each length in turn becoming of north and south polarity, is novel, and will greatly help the adoption of this system in preference to those where two sets of exposed rails are required to close the magnetic circuit. The arrangement of blind rail, which performs the same office as if it were on the surface of the road and under the direct influence of the magnet pole, is very ingenious and effective.

The mechanical strength of the magnetic channel and of the line generally, was tested by taking a steam roller over it. The line was not damaged thereby in any way, either mechanically or electrically, and I consider the result of this test highly satisfactory.

As a general result of my investigation, I have come to the conclusion that the Lineff closed magnetic channel system is now ripe for practical application.

## APPENDIX TO REPORT.

The tests upon which my report is based were made on the 29th and 30th of May, and the 3rd, 10th and 11th of June, 1890.

I deal in this appendix with the various points in the same order in which they occur in the report.

## SAFETY TO THE PUBLIC.

The extent of "charged region" on the insulated rail was tested in the following manner:—The positive lead feeding the glow lamps on the car was disconnected from the main positive terminal, and connected to a flexible conductor terminating with a contact piece or pilot brush. The latter was attached to a wooden bar which could be set so that contact was made with the insulated rail at any given distance from the centre of the car. When the point of contact was on a charged or "live" rail the lamps lighted up; when on a "dead" rail they remained dark. By varying the distance of contact it was thus easy to ascertain the extent of the charged region on either side of the centre of the car. I found that the length of charged region varies at different points of the line, which may be due either to a variation in the thickness of the hoop iron (this being of two different gauges on the line), or to a variation in the thickness of its zinc coating, which, if too thin, would not allow the hoop to drop instantly. I also found that there was some uncertainty in the lamp test if the contact between the pilot brush and live rail lasted only a fraction of a second. In such cases the lamp filaments had not time to become so hot as to be distinctly visible, and I replaced in subsequent tests the lamps by an electric bell, which gave indications with contacts of so short duration as to escape detection by the lamp test. The result of these tests, which were made at various speeds, and over a continuous piece of line 68 feet long, are given in the following table.

Extent of Charged Region behind the Centre of the Car.	Speed in Miles per Hour.			
	1	8	7	
7 feet 6 inches ... ..	live	live	live	live
8 " 3 " ... ..	live	live	live	live
8 " 6 " ... ..	live	live	live	live
9 " 0 " ... ..	dead	dead	dead	dead
9 " 6 " ... ..	dead	dead	dead	dead
10 " 0 " ... ..	dead	dead	dead	dead

There remained still the question whether the wave running along the hoop iron under the car might induce subsidiary waves in it at greater distances than 10 feet from the centre, either in front or behind the car. If this were the case, there would be danger of the magnetic rail becoming "alive" at points when ordinary traffic passes over it. I have tested this question by short-circuiting the magnetic rail to earth at various distances both in front and behind the car, and whilst the latter was running and standing, and in no single case have I found a "live" section of magnetic rail.

I also investigated the question whether it will be possible to collect the current from the magnetic rail without sparking, as otherwise horses might be frightened. In the original management, the collection of current was effected by the contact of the wheels supporting the electro-magnet on the magnetic rail, and with a dry and clean line, or with a dirty and wet line, there was no perceptible sparking. If, however, the line, when dry, was

covered with dry sand, gravel, and clinkers, there was sparking, and to avoid this defect, I advised Mr. Lineff to fit wire brushes to the pole shoes, so as to obtain more perfect contact. This has been done, and in a subsequent test no perceptible sparking occurred with any condition of line.

#### EFFICIENCY OF SERVICE.

The efficiency of service depends upon the power required to propel the car, and upon the possibility of maintaining the line in proper working order. As regards the power required for the car itself, apart from that absorbed by the apparatus for collecting the current, there is no reason why the Lineff car should require either less or more power than any other electric car of equal weight, and geared to run at the same speed. I have therefore only to investigate what extra amount of power is absorbed by the apparatus for collecting the current, and what amount of power is lost by underground and surface leakage.

The power required for the current collecting apparatus may be regarded as lost to propulsion, and this loss consists of three items:—

#### 1.—Imperfect Contact between Magnetic Rail and Wheels of Electro-Magnet.

I measured the difference of potential between the magnetic rail and the car terminal when the working current of 11 amperes was passing. The drop of E.M.F. thus found varied with the condition of the line. It was .3 of a volt when the line was watered, but otherwise clean; .7 when the line was clean and dry; and 2.7 when the line was dirty with mud, horse dung, sand and clinkers. These tests were all made before the brushes above mentioned had been fitted, so that with the improved contact this loss of power may be considered as insignificant.

#### 2.—Power Required to Energise the Electro-Magnet.

The resistance of the two magnet coils and a third external coil is 220 ohms, and the working pressure 230 volts. The power absorbed in the three coils is therefore  $\frac{230}{220} \times 230 = 240$  watts, of which 160 watts are required for the magnet and 80 watts wasted in the external coil. These 80 watts could be saved by rewinding the two magnet coils with finer wire. The energy expended in "picking up" is therefore 160 watts.

I had previously tested the magnet and found that 60 watts is the minimum of energy required for picking up, but to make sure of always maintaining the circuit, 160 watts have been allowed. During my test of the line, there has been no case of failure to maintain the circuit.

#### 3.—Power Required to Propel the Electro-Magnet.

This was tested by hauling the magnet alone along the line, a spring balance being inserted into the hauling rope. I found the resistance to be 19 lbs. when the magnet was not energised, and 27 lbs. when it was energised. At seven miles per hour this represents an expenditure of about half a horse power. It appears desirable that this loss of power should be reduced, which can be done either by employing larger wheels and improved axle bearings on the electro-magnet, or by so suspending it from the car, that part of its weight is taken by the car.

In the workshop there has been erected a full size working model of the magnetic rail as arranged for a switch or branch line. After the tests on the line on the 30th May were completed, the electro-magnet was detached from the car, taken into the workshop, and run over the magnetic rail containing a branch line. The current-collecting apparatus acted perfectly, and there was no failure to maintain the circuit either on the main or on the branch line.

#### ECONOMY OF WORKING.

I have now to consider the amount of power lost by underground and surface leakage. The former takes place over the whole length of the line, and is independent of the number of cars in use at any time, whilst the latter is confined to the three charged sections of magnetic rail under each car, and is therefore proportional to the number of cars in use at any time. The insulation resistance of the conductor was tested both by the bridge method (48 Leclanché cells, Post Office pattern bridge, and mirror galvanometer), and by passing the leakage current through a voltmeter. The two methods gave fairly accordant results, but the insulation varied on different days considerably. The highest reading I recorded by the voltmeter test, when the full pressure of 230 volts was on the conductor, was 5,400 ohms, and the lowest 3,550 ohms. In order to maintain the underground conductor in a proper working condition, I consider it desirable and possible to increase its insulation resistance. But for the determination of loss of power by leakage, I take the figures as I find them, disregarding any future possible improvements in insulation. From these figures it appears that the average insulation is 4,475 ohms. Since the line is 220 feet long, the insulation resistance of one mile of similar line will be 186 ohms. Assuming the working pressure to be 300 volts, the leakage current would be 1.61 amperes, and the power thus lost would be 482 watts, or about two-thirds of a horse-power. This loss in itself is not an important item. It is, in fact, negligible in comparison with the power which is required for the propulsion of the cars on a mile of line.

Another source of loss of power in electric traction is surface leakage. To ascertain this, I also applied the voltmeter test, and found the following insulation resistances of three charged sections

of magnetic rail. With the line clear and moist, 4,183 ohms with the line very wet and covered with mud and horse droppings, 980 ohms. Taking 2,000 ohms as an average, I find that at a working pressure of 300 volts, the loss of power by surface leakage per car amounts to 45 watts, which is quite insignificant.

As regards the question whether it will be possible to maintain the line in proper order when subjected to the wear and tear of ordinary street traffic, I am of opinion this can only be decided by actual trial extending over a considerable time. As far as it was possible to do so, in an experiment extending over a few days, I have tested the line both as regards mechanical strength and insulation. I have already mentioned that the resistance varied between 5,400 and 3,350 ohms during the time over which my experiments extended. An average insulation of 4,475 ohms per 220 feet, or 186 ohms per mile, would not be too low if the only consideration were that of the waste of power entailed by leakage, but experience shows that when the insulation of a line is initially low, there is probability of its becoming still lower in the future, and for this reason I consider it desirable to improve the insulation of the line. I am of opinion that this can be done in two ways—first, by an alteration in the shape and arrangement of the earthenware supports of the conductor, and, secondly, by blowing dry air through the channel. This will necessitate the employment of air compressor at the power station, but the additional capital outlay and working expenses will be trifling in comparison with the advantages of good insulation, which will be obtained thereby. The mechanical strength of the closed channel was tested by taking a steam roller both across and along the line. Since the magnetic rail is slightly higher than the running rail and surrounding pavement, the whole weight on one of the driving wheels of the steam roller (which I estimate at 5 tons) was thus supported by the magnetic rail. The steam roller was driven backwards and forwards, over and across the magnetic rail, to see whether any mechanical damage could thus be done to it. I could not detect any deformation or other damage done to the magnetic rail or the bitumen channel, and, so far, the steam roller test was entirely satisfactory. There remained still the possibility that, through the application of a concentrated pressure of 5 tons, minute cracks, invisible to the naked eye, might have been developed which would admit moisture, and thus impair the insulation. To test this point, I had the line drenched with water, but, as shortly afterwards it began to rain, I discontinued the artificial application of water. The rain lasted on and off during the remainder of the day and following night, and in the afternoon of the following day I had the insulation of the line again tested by my assistant. He reported 3,400 to 3,800 ohms. Before taking the steam roller over the line the insulation was 3,400 ohms. If the mechanical strain had developed cracks in the bitumen, there would have been sufficient time for water to percolate in the interval of 26 hours which elapsed between the two resistance tests. Since, however, the second test showed the same if not a higher insulation than the first, it is evident that no damage was done to the line by the steam roller, and I consider the result of this test very satisfactory.

## THE ELECTRIC LIGHT AT BATH.

SEVERAL deputations from representative bodies in London and the provinces have visited Bath to inspect the electric light works and the public arc lamps. A serious leak which occurred on the night of the 8th inst. affected more or less 40 out of the 81 public lamps. Directly the leak was discovered, steps were taken to localise its position, but, owing to the very short nights, this was not completed until nearly the time for ceasing lighting. In reporting the mishap to a committee of the Town Council, Mr. Massingham wrote: "The leakages that I have discovered so far are due to the movable connections between the underground mains and the lamps for the purpose of raising and lowering the lamps and so dispensing with ladders. Major Cardew, R.E., recently inspected the whole of the electric installation on behalf of the Board of Trade, and appeared extremely well satisfied with it as a whole, but suggested that it would be impracticable to make the raising and lowering arrangements absolutely safe, and advised my adopting fixed lamps and conductors and using ladders to reach them, which would be far more reliable from an electrical point of view. As the practical experience of the past fortnight confirms his views, I have decided to dispense with all movable arrangements, and have given instructions to Messrs. Callender & Co., who laid the underground mains, to carry this out with all possible speed. The work is now in hand and, I hope, will be finished within three weeks." The letter was regarded as satisfactory. The Christopher Hotel is lighted by means of electricity from the Bath Electric Light Works. The light is also being introduced into the York House Hotel.

**Accumulator Question in Paris.**—The adoption by the Northern Tramway Company in Paris of the the Société Française d'Accumulateurs Electriques system has been followed by an order for 40 more cars.

## THE COMPOUND WINDING DYNAMO MACHINES.

KING, BROWN & Co. v. ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION.

IN the Court of Session, Edinburgh, on Wednesday, the 16th inst., the First Division disposed of a reclaiming note in the above case. It was originally brought in the Outer House by King, Brown & Co., Rosebank Electric Works, Edinburgh, against the Anglo-American Brush Electric Light Corporation, London and Edinburgh, for reduction of letters patent granted to Mr. Brush in 1878 for the exclusive right of making dynamo-electric machines of the compound winding type. Lord Trayner, in the Outer House, found that Brush's patent, having been anticipated by Varley, was invalid, and he, therefore, decided the case in favour of the pursuers, with expenses. The defenders reclaimed to the First Division of the Court, and the case was heard before the Lord President, Lord Adam, and Lord McLaren. Judgment on the reclaiming note was given on Wednesday.

Lord McLaren said: The defenders, the Brush Electric Light Corporation, claim under their patent the exclusive privilege of making dynamo-electric machines, in which the electro-magnets are of the type known as "compound wound" magnets; also known as the "series shunt" type. The pursuers, King, Brown and Co., are makers of "compound wound" dynamos; and their right to make such machines having been extrajudicially challenged they have brought this action to have the defenders' patent reduced and declared void on various grounds; the chief objection being that the invention of compound winding was previously discovered and made known by Mr. Varley, and consequently that Mr. Brush, or his assignees, are not in the position of being the "first and true inventors" of this valuable electric appliance. There can be no doubt that the holders of Brush's patent claim compound winding as an essential feature of their machine; and, accordingly, if this claim be ill-founded, the patent must fall. The argument was directed mainly to the question of the anticipation of the Brush system of compound winding by Mr. Varley, and I shall consider this subject in the first place, touching afterwards on the objections to Brush's specification, which are of a technical character. In order to make my observations intelligible, I must begin by stating in what compound winding consists:—When the armature of an electro-magnet is attached to an axis, so as to be capable of rotating in the magnetic field, the armature tends to place itself in a symmetrical position with reference to the poles of the magnet, and if force is applied to turn the armature on its axis, the movement of rotation is resisted by the forces in the magnetic field. The energy expended by the steam power, or whatever power is employed to turn the armature against the resistance of the magnetic field, is then converted into current electricity; and the current being carried through the revolving axis by insulating wires, is given off by an appliance termed the commutator, passes thence into a conducting wire, and is then ready to be used for electric lighting, or any other purpose of utility to which it is capable of being applied. In the rudimentary form of the dynamo machine, I understand that the excitation of the electro-magnets was maintained from a separate, or, as it is termed, an external source, generally a battery of some kind. The first improvement consisted in winding one of the conducting wires round the electro-magnet, the continuation of this wire being led into the external or working circuit. In this way the current flowing from the dynamo was made to maintain the magnetism of the electro-magnets as a part of the work which it had to perform. This is known as series winding, because there is one continuous current which is only partly used in maintaining the magnetism. The next improvement consisted in dividing the current as it flowed from the commutators into two partial currents. In this system the wire is bifurcated; one branch is wound round the electro-magnet, and is returned to the opposite poles of the commutator. The second branch wire is employed for lighting or external work of some kind, and is reunited to the first branch wire near where it meets the commutator at the opposite pole. This is the form known as the shunt winding system, or shunt machine. The invention of compound winding, with which we are here concerned, consists in, I will not say a combination of the two methods, but in the addition of the shunt and series method. The wire is divided or bifurcated as it leaves the commutator. Both the branches are wound round the electro-magnets. One of these is directly returned to the opposite pole of the commutator without doing any work other than the excitation of the magnets. The second wire, on leaving the electro-magnets, is continued to form the external or working circuit, and is ultimately re-united to the first wire. This arrangement seems to be an exception to the rule against trying to do two things at the same time, because it is admitted that the compound wound machine is a much better working machine than the shunt. It appears that the sections of the wires can be so proportioned that an early uniform current flows in the working field, notwithstanding variations in the quantity of work to be done. It is not necessary for the purposes of the case to explain why this should be, and if it were necessary, I am not sure that I am able to explain it. It is a question of the mathematical theory of current electricity. But it is agreed that the compound wound machine, when the wires have the proper relative conducting capacity, gives better results as regards uniformity and steadiness

of the current than are attained by either the series or the shunt, and this explains the importance of the right to use this invention to the parties concerned. I may here observe it is not clear to me that either Varley or Brush were at first fully aware of the scientific and practical importance of the principles of compound wiring. Varley was the inventor, or one of the inventors, of the "series" machine, and both Varley and Brush were doubtless aware of the advantages and disadvantages of the "series" and the "shunt." The idea of introducing the two methods into the same machine is one that would very naturally occur to any one familiar with the subject, and practically conversant with dynamo machines. Assuming that this is intelligently done, with the object of getting a better working machine through the union of the series and the shunt than is attainable by either of these modes of winding singly, then the invention is a proper subject of a patent, and it is not necessary to its validity that the patentee should have foreseen all these advantages which have been realised through the subsequent introduction or extension of electric lighting with the incandescent lamp. I may also observe that in Brush's specification, as well as in this specification, the mode of winding is only treated as one among many other parts of a dynamo machine; and it is quite possible that a reader, even if conversant with the subject, might peruse either of these documents without having his attention specially called to the novelty of the system of compound winding. But neither will this consideration affect the question. An inventor may describe his invention clearly without proclaiming it as a very important discovery, and the question is whether compound winding is clearly described in Varley's specification. The specification in question is No. 4,905 of 1876, and its title is—"Improvements in apparatus for producing the electric light, parts of which invention are applicable to other purposes." The alleged anticipation is contained in the two paragraphs, page 4, lines 11 to 21—"Part of the electricity developed by the machine is diverted to maintain the magnetism of the soft iron magnets, and the remaining portion is used to produce the electric light." I interrupt the reading to remark that in the words I have read the writer only announces what he is going to do, and does not profess to be explaining his method. This obvious, and I should have thought, superfluous criticism disposes of many pages of evidence in which witnesses are brought to say that these words would not give them a clear idea of the method of winding. The specification proceeds—"There are several well-known ways of doing this" (that is, of diverting a part of the electric energy developed by the machine), "but the method I prefer is to wrap the soft iron magnets with two insulating wires, one having a larger resistance than the other. The circuit of larger resistance is always closed, and the circuit of less resistance is used for the electric light." If the description had stopped here I should not have doubted that it contained a clear description of the construction of a compound wound machine—I mean a description of so much of the apparatus as is included in the name compound winding. The direction is to wrap the magnets with two insulated wires. It is, of course, implied that these wires are to carry currents coming from the machine; but this is not left to implication, because it is clearly explained that these insulating wires are the media for the transmission of separate currents, the one of larger resistance being always closed (in other words, acting as a shunt); while the other is used for the electric light (having previously contributed to the magnetisation of the magnets by being wrapped around them). But if the description had stopped here it would have been open to the observation that while it described the construction it did not indicate, except in a very general way, the use of the compound winding of the magnets. Now, I could hardly consider that to be an adequate description of an invention which should leave the reader in ignorance of its utility and its mode of action. But the information which I desiderate is supplied by the second paragraph: "When the electric light is being produced the greater portion of electricity passes through the circuit of less resistance, which I term the 'electric light circuit,' maintaining the magnetism of the magnets, and producing the light. When the electric light circuit is open from any cause, the electricity developed passes through the circuit of greater resistance only, and maintains the magnetism of the magnets." There is here plainly described one of the advantages of the compound wound dynamo, probably the only one known to the writer, viz., that when work is being done in the external circuit, the magnets have the benefit of the unobstructed flow of the electric current through the wire of larger resistance and less resistance, while when the external circuit is open and no work is being done, the magnets receive through the wire of greater resistance the current, which is sufficient for their excitation. I am here merely paraphrasing Mr. Varley's description without meaning to add anything to it, and I think that anyone conversant with the subject, and reading this paragraph (whether he agreed with Mr. Varley or differed with him as to the possible benefits to be obtained), would not be left in doubt as to what Mr. Varley considered to be the rationale, and the mode of action of the arrangement of wires described in the preceding sentences. I have difficulty in understanding how it is that a considerable number of able and distinguished men should have been persuaded to give their evidence as to the alleged insufficiency of Mr. Varley's description as an anticipation. To a considerable extent the evidence of the witnesses of the Brush Company is made up of somewhat minute and verbal criticism on the expressions used by Mr. Varley. But, in so far as these gentlemen indicate an opinion as to the insufficiency of the description in its entirety, I think their conclusions are, in part, explained by their having misapprehended the question, because I observe that

the question is frequently asked, and answered, whether Varley's specification is such as would enable an ordinary workman to make a compound wound machine. Now the question of anticipation does not depend (in our opinion) upon that test. We are not here trying the sufficiency of Varley's specification as a specification. Varley is not here claiming any exclusive privilege (his patent has long since expired), and we have no occasion to consider whether he fulfilled the duty which is the counter-part of the exclusive privilege given to a patentee of particularly describing and ascertaining the nature of his invention, and the manner in which it is to be performed. I am very far from saying that Varley's specification is insufficient as a specification of a patented invention. I rather think it would be held to meet the requirements of the statute of King James. But the question we are now considering is quite different: it is whether Mr. Brush is or is not the first and true inventor of compound winding; and the negative of that proposition may be proved by showing that the invention was previously described, not necessarily in language sufficient as a direction to a mechanic; but in language clear and intelligible to educated men conversant with the subject, and capable of giving the necessary directions to the hypothetical workman. An invention may be clearly described in mathematical or chemical symbols; the latter being, perhaps, the preferable illustration. Such a description, although it may have to be translated for the instruction of the operative chemist (just as if it were written in a foreign language) would be an anticipation of the same invention described in popular language, such as is required (as far as practicable) by our Patent Law. Now I venture to think that if Varley's description had been put into the hands of any of the defenders' witnesses (without reference to any question under the Patent Laws) that he would have understood it, and would have been able to instruct a workman to make an experimental machine. I think I can collect from their evidence that the witnesses on both sides understood the specification perfectly, although some of them were certainly apprehensive that other persons, less gifted, would not find it so easy to be understood. It is a remarkable circumstance in this case that neither in the course of the trial, nor in the argument addressed to us, has any reference been made to Brush's description of compound winding. It seems to have been assumed that it, at least, was a pattern of clearness, and certainly no objection was taken to it on the ground of insufficiency. Brush's description is contained in the following passage in his specification:—"In applying my invention to dynamo-electric machines, I wind the cores of the field magnets with a suitable quantity of a comparatively fine wire, having a high resistance in comparison with that of the external circuit, and the rest of the wire in the machine. The ends of this wire are so connected in the other parts of the machine, that when the latter is running a current of electricity constantly circulates in said wire, whether the external circuit be closed or not. The high resistance of this wire prevents the passage through it of more than a small proportion of the whole current capable of being evolved by the machine; therefore the available external current is not materially lessened. When this device, which I have called a 'teaser,' is used in connection with field magnets, also wound with coarse wire for the purpose of still further increasing the magnetic field by employing the main current for this purpose in the usual manner, then the 'teaser' may be so arranged that the current which passes through it will also circulate in the coarse wire, thus increasing the efficiency of the device." Now if Varley's description be insufficient, I do not see how the validity of Brush's patent can be maintained, because the two descriptions are practically identical. Conversely, if the invention of compound winding be well described in Brush's specification, the identical description in Varley's specification must be an anticipation. I do not mean, of course, that the language of the two descriptions is absolutely identical. In describing the shunt arrangement, Brush calls it a "teaser" (I do not know whether electricians attach any significance to this vocable), and there are some other variations of expression. But I can find nothing of substance in Brush that is not in Varley, and I cannot help adding that if there be any difference Varley's description is the more easily understood of the two. This completes what I have to say on the subject of anticipation by prior publication. There is also a plea of anticipation by prior use. On this point the facts are these:—In the interval between the filing of the provisional and complete specifications Mr. Varley had a machine made to his direction by the firm of Siebe and Gorman. When the machine was first tried it did not work well, because its frame was not sufficiently strong to prevent the revolving armature being attracted into contact with the electro-magnets. I need not say that the motion of the armature must not be resisted by friction, but only by the immaterial, though not less real resistance offered by the forces developed in the magnetic field. This was corrected by strengthening the frame, and the machine was successfully used in the production of an arc light by the lamp produced along with the machine. Siebe and Gorman are makers of diving apparatus, and the lamp was used on their premises to exhibit the apparatus under water in a tank which they had for the purpose. The case on public use is narrow, but we consider that what I have described is public use as interpreted by decisions. The machine in question was produced, and it is a compound machine; nobody has said anything to the contrary, though some of the defenders' witnesses say that if the wires were uncoupled, or were coupled up in a difficult way, it would no longer be so. But the effect of uncoupling the shunt wires would be to render this part of the winding simply useless for any purpose, as would indeed be the case with a machine of any kind if a material part

of the mechanism is taken out of its place or turned the wrong way. The Lord Ordinary has, in his judgment, extracted some of the more noticeable expressions of opinion by the scientific witnesses on the questions of prior publication and prior use, and has pointed out the insufficiency of the reasons given for holding Varley's specification to be incorrect or incomplete. I concur in the Lord Ordinary's view as to the weight to be attached to this part of the evidence, and, in his lordship's opinion, generally on the facts of the case, except in so far as he may be held to imply that the test of the sufficiency of an anticipation is the same as the test that would be applied to the construction of a specification founded on as such. There is another objection to the defenders' patent, and it is founded on an alleged inconsistency between the provisional and the complete specifications. The provisional specification announces, as one of the improvements for which the patent is granted, an improved construction of the commutator. The function of the commutator is to convert the alternating currents (as they pass from the revolving axis to the external circuit) into one continuous current. This is accomplished by fitting the axis with insulated segments, to which the poles of the armature are connected by insulated wires, and these segments are so arranged that at the moment when the current in the machine is reversed, the external wire becomes disconnected from the corresponding segment, and is at the same time brought into connection with the segment which is attached to the opposite pole of the armature. The improvement indicated in the provisional specification is a purely mechanical improvement for the purpose of obtaining a mechanical advantage. But, in the course of perfecting his invention, Mr. Brush found that an electrical advantage might also be secured by means of a slight variation of the mechanical arrangement indicated in the provisional specification. The variation consists in separating the segments, so that for a small fraction of each semi-revolution the current shall be interrupted; that is to say, the current is cut off during the brief interval when the armature (or the particular member of the compound armature) is in a neutral position, and when the resultant of the forces acting on it is therefore very small. In the complete specification, the variation whereby this electrical advantage may be gained is claimed as one of the patented improvements, and the question arises whether this difference between the provisional and complete specifications does not exceed the latitude allowed to an inventor who is only perfecting what he has provisionally announced. The Lord Ordinary has held that the claim referred to is not covered by the provisional specification on the ground that, although the construction of the commutator as perfected is not materially varied, yet, as the variation represents a distinct principle, and is directed to an object distinct from that which is indicated in the provisional specification, the two things cannot be regarded as identical inventions. There is much force in the Lord Ordinary's view on this question; but we consider it unnecessary to come to a decision upon it, because we are all of opinion that if there had been no more serious objection to the Brush patent than this, it would be only fair to the patentee that he should be allowed an opportunity of disclaiming this variation on one of the patented improvements. But this is not the condition of the case as it arises for decision, because we are agreed that the patent is invalidated in its essential and fundamental privilege by reason of the prior publication and prior use by Varley of the invention of compound winding, for which this exclusive privilege is given. For these reasons I am of opinion that the interlocutor of the Lord Ordinary should be adhered to, and decree of reduction of the patent pronounced.

THE LORD PRESIDENT: That is the opinion of the Court.

On the motion of Mr. DANIELL, counsel for King, Brown and Co., the Brush Corporation were found liable in expenses.

## PROCEEDINGS OF SOCIETIES.

### The Institution of Electrical Engineers.

"Observations on Currents originating in ordinary Aerial Telegraph Conductors,"\* by A. R. BENNETT, Member.

All users of telephones connected by single wires are familiar with the variety of noises which are generally present, even when the line is only a few hundred yards long. It is exceptional to find a wire which can be said to be even approximately silent at all times. The origins of some of the foreign currents which the presence of these noises indicates, have been explained by Preece, Lockwood and others. Recently in testing some overhead copper and iron wires run on the same poles for capacity by charge and discharge, using a sensitive reflecting galvanometer, the author noticed the presence of currents which could not be accounted for by any of the known explanations, and the causes of which he determined to investigate.

It was noticed that soon after the commencement of rain, a steady current appeared on all the wires under test. The deflections increased as the rain continued, until, after the thorough soaking subsequent on several days' wet, they were in some cases no

\* Paper read at the special meeting of the Institution of Electrical Engineers, held in the Lecture Hall, Edinburgh International Exhibition, July 15th, 1890.

longer within range of the scale. A constant discrepancy in the behaviour of copper and iron wires was apparent. The deflections from the copper were always positive, while those from the iron were always negative, and as invariably much feebler, seldom exceeding one-third the strength of the positive ones.

To ascertain the cause, two wires, one No. 12½ copper, and the other No. 11 galvanised iron, run side by side on the same arms for the distance of a mile (fig. 4) were taken. In fine weather the insulation resistance of each was infinite.

When disconnected at the farther ends and earthed at the home end through the reflecting galvanometer (fig. 1), they always in wet weather exhibited the phenomena described.

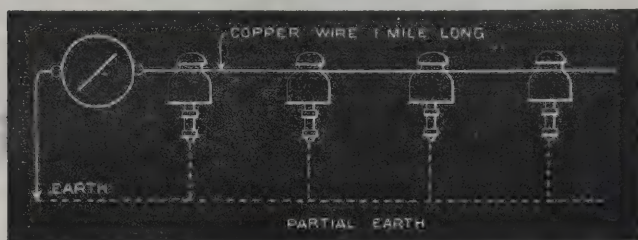

FIG. 1

The following are extracts from the records of tests extending over several months, during medium and heavy rain:—

Copper.—Always positive.		Iron.—Always negative.	
Degrees.	Value of deflections in milliamperes.	Degrees.	Value of deflections in milliamperes.
4.5	.0030375	1.5	.0010125
13	.008775	3.75	.00253125
20.5	.0138375	4	.002700
17	.011475	3	.002025
15	.010125	4.5	.0030375
3	.002025	.5	.0003375
46	.031050	17.5	.0118125
22	.014850	7	.004725
14.5	.0097875	3.5	.0023625

It will be observed that the copper deflections were always from three to six times stronger than the iron ones. When the copper and iron wires were left insulated at their distant ends, and looped through the galvanometer (fig. 2), earth being excluded, the positive and negative deflections were always equal. Thus, taking the last three of the foregoing tests, when looped 46 + 17.5 — became 35 + 35 —; 22 + 7 — became 12.5 + 12.5 —; 14.5 + 3.5 — became 9.7 + 9.7 —.

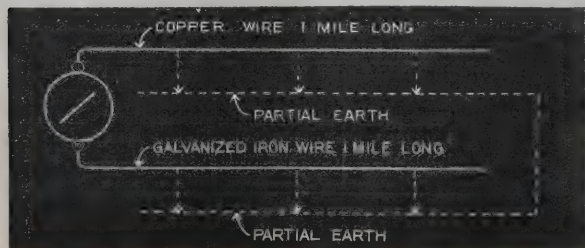

FIG. 2.

Half-a-dozen insulators with galvanised iron bolts were mounted on an arm in the testing room, and thoroughly wetted (fig. 3). With a copper wire run on them, and the bolts connected, as shown, a positive current appeared as soon as a film of water was established between the wire and the bolt. With an iron wire instead of the copper no current appeared.

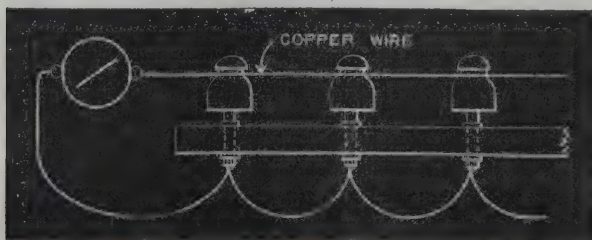

FIG. 3.

The positive current, therefore, seemed to be due to voltaic action between the copper wire on the insulators and the galvanised iron bolts supporting them when connected with the moist surface. The course of the current can be traced in fig. 1. The

wire and insulator bolts form a series of voltaic cells joined in parallel.

The absence of a current from the iron when mounted on the experimental arm confirmed this conclusion, since no current was to be expected under the conditions. But whence, then, the negative current from the iron wire run on the actual poles? In that case it had a copper wire strung alongside it (fig. 4). The wetting of both insulators established the connection necessary for electrolytic conduction between them, so that the metals constituted a voltaic couple, the negative current from which appeared on the iron.

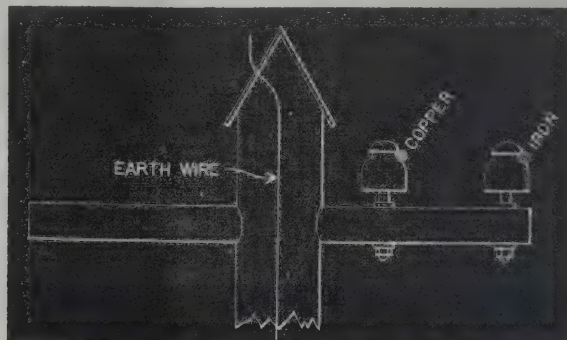

FIG. 4.

The positive current on the copper was consequently due to the copper wire acting with the iron bolts of its own insulators, the iron bolts of the neighbouring insulators and the iron wire which they supported.

The negative current on the iron was due to the iron wire, its bolts, and the bolts of the neighbouring insulators, acting with the copper wire. But the bolts of the insulators (fig. 4) were partially earthed by the damp wood of the poles and the earth wires which ran down them. If the earth had been perfect no current could have got to the galvanometer, but since it was only partial some found its way by that route; and so the difference in strength between the positive and negative currents is accounted for.

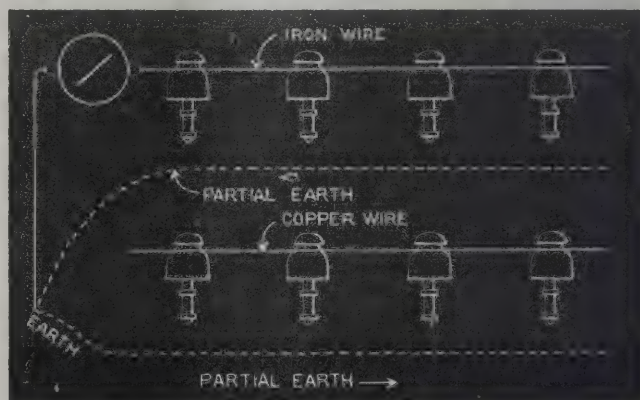

FIG. 5.

The positive, depending chiefly on the action between the copper wire and its own bolts, between which no earth intervenes, is necessarily stronger than the negative, which depends wholly on the action between the iron wire and bolts and the copper wire between which a partial earth is interposed (fig. 5). So when the earth is cut off from the galvanometer (fig. 2), the effect of the earth between the two plates is neutralised, and the positive and negative deflections become equal.

A somewhat unexpected effect of the recent introduction of copper wires for telegraph and telephone purposes is consequently the establishment over the country of a vast number of voltaic couples, which only become operative in damp or wet weather.

The zinc of the bolts of insulators carrying copper and bronze wires may reasonably be expected to disappear sooner than in days gone by when only iron wire was used; and when copper and iron wires are run on the same poles the galvanising of the iron must suffer sooner than of yore.

The Americans, with the wooden pins, will escape the currents due to the difference of metal between the wire and its supports; but when they mix wires of different metals on the same poles the resulting action will be stronger than with us, since they do not earth-wire their posts.

Telephonically, the existence of these currents is of little moment. With metallic loops when both wires are of the same metal, they will not matter at all, since the currents from two similar wires will be in the same direction and of the same strength, and, meeting in the telephone or translator will neutralise one another.

On single wires, so long as the currents remain steady, their presence does not matter much. As they increase gradually as the insulators become wet, and die away slowly as they dry, they

do not give rise to any disturbance in the telephone. If any confirmation of the voltaic origin of these currents were needed, it would be afforded in the fact that it is possible by changing the line from a battery, to polarise the line couple even to the extent of obtaining temporary currents of the opposite sign. Thus, the copper was repeatedly changed from a 90-volt battery; when from the positive pole the line current was increased, when from the negative the line current was decreased and sometimes reversed.

The following are particulars of several tests of the copper wire, the deflections being in degrees:—

Charging wire from 90 volts, &c., to line so as to neutralise and overcome line current.

Line current.	Duration of charge.	Result.
5 +	10 seconds.	Reversed to 2 -
6 +	20 seconds.	Reduced to 5 +
8.4 +	4 minutes.	Reduced to 3.5 +
12.5 +	10 seconds.	Reversed to 2 -
		Spot went back instantly to 5 +, and then recovered slowly to 12.5 +
12.5 +	20 seconds.	Reversed to 4 -
		Went back quickly at first, and then slowly recovered to 12.5 + in 45 seconds.
12.5 +	1 minute.	Reversed to 8 -
		Went back instantly to 3.5 +, recovering slowly to 12.5 in 70 seconds.
12.5 +	2 minutes.	Same as 1 minute.
12.5 +	3 minutes.	Same as 1 minute.

The same effects were produced with the experimental arm. With only one insulator, reversed, the cup being full of water and the surface well wetted, a deflection was got of 4 degrees, equal to .0027 milliamperes. When the current from this insulator was reduced to 2 + through the surface drying, a reversal could always be obtained to 4 -, and sometimes to 6 -, by charging it from 90 volts -.

During the capacity tests already mentioned, it was observed that for some time after the commencement of rain, the apparent capacity of the wire invariably rose, instead of falling with the decrease of insulation. This effect has, of course, been noticed before, but, as the author was not aware that it had been satisfactorily accounted for, it was resolved to investigate, and the result of the investigation seems to point to several contributory causes. Firstly, no doubt, the line current due to the voltaic action already described will increase or diminish the discharge according to the direction of the charging current. Secondly, the polarisation of the bolts due to the charging current will have the same tendency. But the capacity of the line will appear too high when the moisture on the insulators is too slight to permit of voltaic action. To seek the cause of this, 12 feet of copper wire was run on six dry insulators fixed in oaken arms in the test room. With 90 volts the wire gave a discharge of .4 degree. The tops of the insulators around the binding wire were wiped with a wet sponge. The discharge then rose to 1 degree, more than double. Wetting more of the surface of the insulators resulted in a still further increase. Several discharges could be got without renewing the battery charge. It would, therefore, appear that wetting the insulators is equivalent to an increase of conductor surface. The moisture has to be charged as well as the wire, and the consequent discharge is greater than with a dry wire. The effect is only observable in moderate rain, or for some little time after the commencement of heavy rain, when the insulators become thoroughly wet the insulation and the capacity fall together, and then the voltaic action and polarisation come into play together with another phenomenon which has not yet been referred to.

Incidentally, in the course of these tests, it was found that when a wire is in contact with moist wood, and is charged from a powerful battery (90 volts were used), the discharge is several times stronger than when the same wire is supported on dry or partially moist insulators. Thus a length of wire on insulators gave a discharge of .9 degree; when fastened along an oaken arm not sensibly damp, with staples of the same metal as the wire, the discharge, after 20 seconds charge amounted to 4.5 degrees, and after 80 seconds to 5 degrees. Then a residual charge appeared to remain in the wood, as the wire continued to yield a current of .5 degree for some minutes, then gradually dying away to nothing.

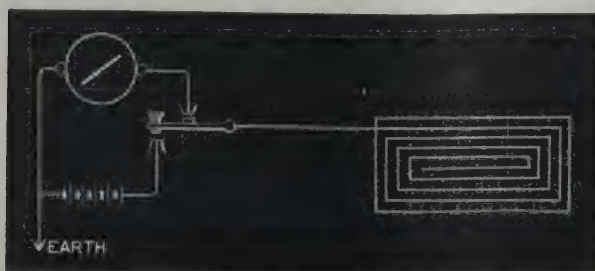

FIG. 6.

Many tests, varied in details, gave the same results; 30 feet of wire in air gave a discharge of .4 degree. When the same wire was stapled on a deal board (fig. 6) not sensibly damp, the discharge became 3.5 degrees, falling immediately to 1 degree, and

then slowly to zero. The wire and the wood were then sponged and the discharge rose to 7 degrees, falling immediately to 2 degrees, and returning slowly to zero. The wire yielded a series of smaller discharges for several minutes without any fresh contact with the battery. A deal box wetted, having some bronze wire in contact with it, was well insulated by being suspended by G.P. Charged for 20 seconds from 90 volts, it gave a discharge of 1.6 degrees, sinking immediately to .8 degree, and then gradually to zero. The same box standing on the floor, gave a discharge, under the same conditions, of 12 degrees, sinking to 3 degrees, and then slowly to zero. The same box touched by the end of an earth wire—also of bronze—well away from the bronze wire, gave a discharge of 45 degrees, sinking immediately to 26 degrees, and thereafter slowly to zero. In the two first cases only one metallic conductor, that is to say, the bronze, through which the charge was communicated, was present, and the source of the return current is not very apparent.

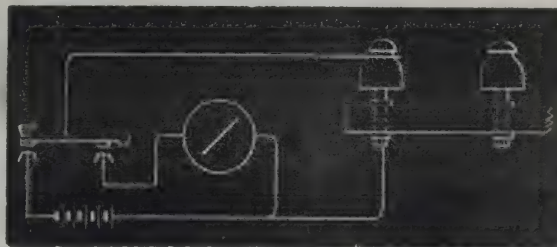

FIG. 7. A.

The last case closely resembles a wet telegraph pole, the earth wire of which does not touch the bolts. Then an expanse of wet wood intervenes between the bolts and the earth, and a powerful charging current in the line must, with leaky insulators, result in back currents. As it is evident that moisture in wood has the effect of increasing the capacity, it may not be unreasonable to deduce that moisture in the air surrounding the wire may have the same effect.

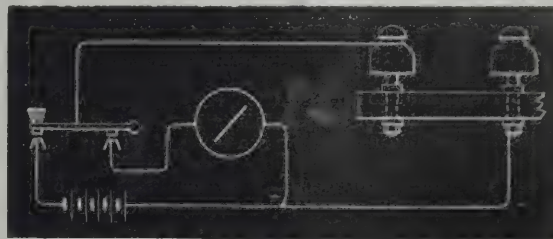

FIG. 7. B.

The foregoing particulars apply whether the line is of copper or of iron; the following observation applies to iron alone.

It has been mentioned that no current between a galvanised iron wire on a wet insulator and the bolt could be detected. But if such a wire is charged by 90 volts, the discharge is followed by

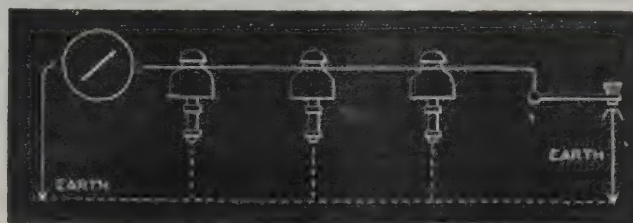

FIG. 8.

a counter current from the insulator. The effect can be produced with a few inches of galvanised iron wire and a wet insulator. As in A, fig. 7. Charging such an arrangement by 90 volts yielded a discharge of .4 degree and a counter current of .3 degree, which did not wholly disappear for some three minutes. Obviously, the polarisation of the bolt following on electrolysis of the moisture made the insulator a secondary battery. The effect of damp wood may be markedly shown by shifting the return wire to the bolt of an adjoining insulator as in B, fig. 7. The discharge then became 1.5 degrees, and the counter current 1 degree, an augmentation of nearly four times.

Connecting the earth wire direct to the bolts will obviate the effect of moist wood, but it increases the strength of the voltaic action and the polarisation of bolts by the charging current.

Although the Americans escape the voltaic action consequent on the use of metallic bolts, the damp wood of their poles cannot be without its effect in wet weather with the insulators they use.

The current set up between copper wire and iron bolts in wet weather might be used to signal with. The experiment has not been tried, but it seems plain that a galvanometer at A, fig. 8.\*

\* There is no lettering on the drawing sent to us.—Eds. ELKO. REV.

through which the line current circulates in its full strength when the wire is insulated at B, would be affected by the working of a key between the line and earth at B, for the key, when closed, would shunt a large proportion of the current away from the galvanometer.

It will be observed that these experiments were made with the distant ends insulated, a condition which does not obtain in ordinary telegraphy. The practical effect of the disturbances noted may be insignificant, especially with double current working, but still it is well to know that they exist.

*Note.*—Since reading the paper it has occurred to the author that the probability of this conclusion—that aimed at in paragraph commencing “The last case closely resembles”—is strengthened by considering that dry and moist air have very different capacities for heat. Tyndall found that the absorption of heat by dry air being 1, that of the air of his laboratory, not specially damp, was 72, while that of air designedly moistened was no less than 90. Thermal and electrical vibrations differ only in frequency, so that some common absorptive action in respect to air may be looked for. The heat absorbed by the moisture in the air is, after the withdrawal of the source of heat, radiated or discharged, not instantly, but gradually, just as the electrical charge, after the cutting off of the battery, is parted with slowly and by degrees, as indicated by the residual charge. It may be expected, therefore, that the apparent capacity of a conductor will be least when contained in artificially dried air.

“The Working Efficiency of Secondary Cells.” By W. E. AYRTON; C. G. LAMB, E. W. SMITH and M. W. WOODS, Associates. Read at Edinburgh, Wednesday, July 16th.

(Continued from page 82.)

#### VI.—RESULTS OBTAINED WITH AUTOMATIC APPARATUS.

Many preliminary experiments having been made with the automatic apparatus, we succeeded in making it work quite satisfactorily by the beginning of May, 1889, and it was adjusted to charge five accumulators, A (fig. 5), with a steady current of 9 amperes until the P.D. reached 2.4 volts per cell, and to discharge them with a steady current of 10 amperes until the P.D. fell to 1.6 volts per cell. After 12 days and nights had been spent in continuous charging and discharging, the cells reached a normal state, the time rise of P.D. in charging and the time fall in discharging being at length repeated over and over again, so that when the time curves were drawn for the successive charges they exactly coincided, and so for the discharge curves. The areas of these curves—reckoned, of course, from the zero of P.D., which is much below the figure as here shown—may thus be said to give the “working watt-hours” for charge and for discharge when the charge and discharge are effected between limits of 1.6 and 2.4 volts per cell. Fig. 6 shows the discharge curves obtained on May 16th, 17th, 18th and 19th, the points for each of the discharges being indicated by points differently marked as stated on the figure; and fig. 7 shows the intermediate charge curves obtained on May 17th, 18th, and 19th. Integrating these curves, we find—

Discharge.		Charge.		Percentage Working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
115	221.8	117	256.2	98.3	86.5

Soon after this very concordant set of results was obtained, the time of charging, which had remained steadily at 13 hours from the commencement of May, began to increase to 15½ hours, while the time of discharge only increased half an hour—that is, to about 12 hours. At first we thought that we had been trying to charge the cells too much, so we stopped the charging when the P.D. per cell rose to 2.35 volts; but the time of charging still continued to increase, until at last it rose to 24 hours, the time of discharge still remaining about 12 hours. On again reducing the P.D. limit on charging, the P.D. per cell now refusing to rise to 2.35 volts, both the times of charging and discharging became very irregular, and at length the time of charging suddenly fell to 10 hours and the time of discharging to 6. On carefully examining the plates, they were found to have badly scaled, and to have suddenly become partially short-circuited; they were therefore carefully scraped, and the mud allowed to settle at the bottom, where, in consequence of the special construction of the 1888 cell, it could remain without short-circuiting the plates. Only a few plugs fell out in this operation. This sediment was afterwards weighed and analysed, showing a composition that will be referred to in Section VIII., on the chemical action.

We now concluded that we had been running the cells too low, and we therefore decided to stop the discharge when the P.D. per cell fell to 1.8 volts, retaining the higher limit of 2.4 volts per cell to limit the charge. It is interesting to notice that Dr. Louis Duncan and Mr. H. Wiegand, in their paper on “The Inherent Defects of Lead Batteries,” read before the American Institute of Electrical Engineers, and which we saw for the first time at the end of June, 1889, reprinted in the *Electrical World*, come to exactly the same conclusion—that the discharge should be terminated at 1.8 volts per cell, otherwise there is a formation of white

lead sulphate and a rapid depreciation of the cell. From what we have since seen, we think that the discharge should be stopped even still sooner—when the P.D. per cell has reached 1.9, or 1.85 volts at the lowest.

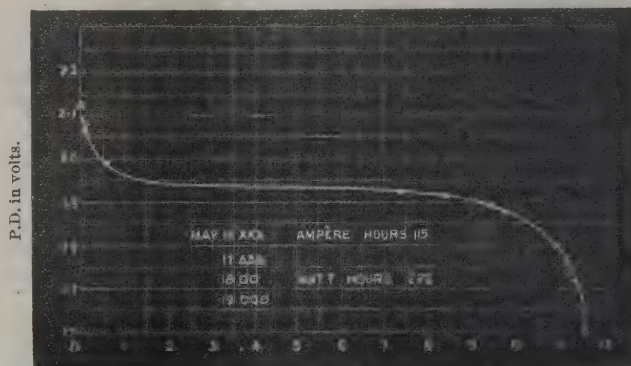

We therefore adjusted the automatic interruptor to stop the discharge when the P.D. per cell was 1.8 volts, and the immediate result of this was to bring the time of charging up to 12½ hours, and to bring up the time of discharging to 10½ hours. After continuing the charging and discharging continuously day and night for 13 days, the cells reached a perfectly steady state. Curve 8 shows the time fall of P.D. per cell in the discharges finished in the early morning of June 19th, recommenced in the night of June 19th, and again commenced late on June 20th, all the three discharges being so precisely similar that they can be represented by one curve; and, similarly, curve 9 shows the intermediate chargings on June 18th, 19th, and 20th, which were also exactly like one another. The times of the three discharges and of the three charges were, respectively, in hours and minutes—

#### TIMES OF SUCCESSIVE

Discharges.	Charges.
10 h. 10 m.	11 h. 38 m.
10 h. 10 m.	11 h. 37 m.
10 h. 11 m.	11 h. 37 m.

showing to what an absolutely definite state cells arrive after a definite cycle of charge and discharge between fixed limits has been repeated continuously without interruption for some weeks.

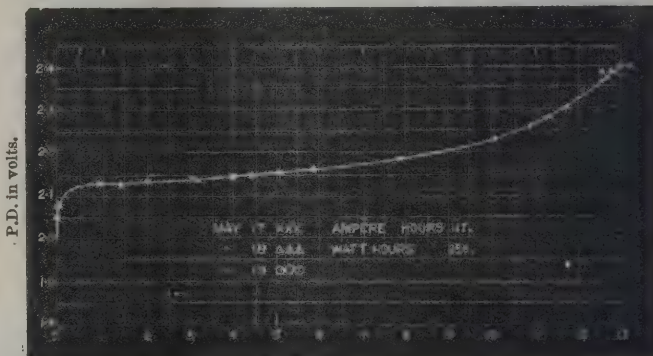

Working potential difference per cell, discharging with 10 amperes.

Time in hours from beginning of discharge.

FIG. 6.

Working potential difference per cell, charging with 9 amperes.

Time in hours from beginning of charge.

FIG. 7.

Integrating these curves, we find—

Discharge.		Charge.		Percentage working efficiency.	
Ampere-hours.	Watt-hours per cell.	Ampere-hours.	Watt-hours per cell.	Quantity.	Energy.
101.9	201.7	104.5	230.7	97.2	87.4

The numbers contained in this last table may probably be considered as giving the steady working values for this size and type of cell. 230.7 watt-hours are equivalent to 612,200 foot-lbs., and as the positive and negative plates of one cell weigh 28 lbs. 10 oz., the working storage capacity is 21,380 foot-lbs. per lb. of plate.

#### VII.—EFFECT OF REST.

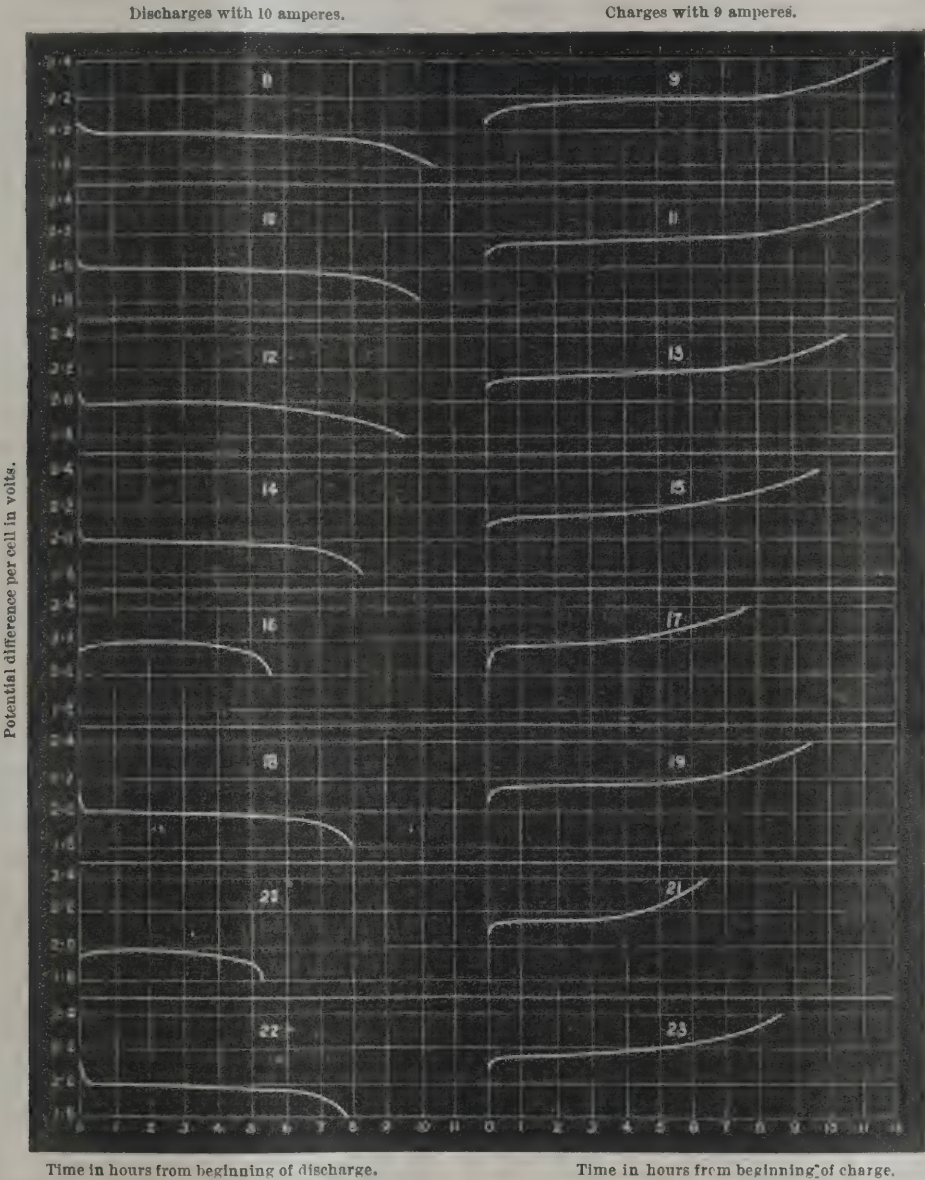

We next tried the effect produced on the capacity and efficiency of accumulators by prolonged rests. The five cells used in the experiments stood on porcelain insulators containing resin oil; and as the insulators, which were specially made for the Central

Institution, were taller than those commonly employed to support accumulators, and as all connecting wires were removed from the cells while they were allowed to rest, it is certain that any change in the cells must have been caused by internal action, and could not have been due to external leakage.

The cells, having been fully charged on June 22nd, were allowed to rest, insulated as above described, until July 2nd—that is, for 10 days. The first few curves of discharge and charge after the rest showed a considerable diminution in capacity and efficiency; but after one week's continuous charging day and night a steady cycle was reached, the following being the times of successive discharges and charges, the limiting P.D.'s, as before, being 1·8 and 2·4 volts :—

August 1st. The first discharge at the end of the rest gave a quantity efficiency of only 80 per cent., so that 20 per cent. of the charge was lost. After a week's continued charging and discharging between the former limits of volts, the cells regained a steady state, but the time of charge and of discharge is now less than before this second rest. The times after the week's charging and discharging were—

Discharges.	Charges.
9 h. 3 m.	10 h. 41 m.
9 h. 2 m.	10 h. 44 m.
9 h. 10 m.	10 h. 51 m.

TIMES OF SUCCESSIVE	
Discharges.	Charges.
10 h. 1 m.	11 h. 35 m.
9 h. 59 m.	11 h. 30 m.
9 h. 58 m.	11 h. 32 m.
9 h. 57 m.	11 h. 33 m.

Curves 10 and 11 show the variation of the P.D. per cell, and on integrating these curves we obtain—

Discharge.		Charge.		Percentage working efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
100	198	103·8	228·2	96·4	85·8

Rest, then, of an accumulator, although left well insulated and fully charged at the commencement, alters the accumulator so that for the first few charges and discharges after the rest it is a much less valuable instrument than before. A week's continuous charging and discharging day and night, however, removes this effect to a great extent; the efficiency, however, still remains somewhat lower than before the rest.

Next, the cells were allowed to rest charged for 12 days, until

Curves 12 and 13 show the P.D. curves when the cells had acquired a steady state, and on integrating them we find—

Discharge.		Charge.		Percentage working efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
91	176·7	96·8	213·2	94·1	82·8

We see, then, that a week's continuous charging and discharging of these cells is unable to compensate for the harm produced by their being left for 12 days fully charged. The two rests of 10 days and 12 days respectively, although followed in each case by a week's continuous charging and discharging, have reduced the discharge ampère-hours by 10 per cent., the discharge watt-hours by 12 per cent., the quantity efficiency by 3 per cent., and the energy efficiency by 5 per cent.

Third Rest.—The cells having been fully charged, a third rest of 16 days took place. On the first discharge, at the normal rate of 10 amperes, the ampère-hours were only 75. After, however, the charging and discharging at the normal rates had been continued for three days and nights, the times of discharging and charging became steady.

TIMES OF SUCCESSIVE

Discharges.	Charges.
8 h. 12 m.	9 h. 28 m.
8 h. 17 m.	9 h. 35 m.
8 h. 19 m.	9 h. 35 m.

and curves 14 and 15 show the working values of the P.D. in discharging and charging. Integrating the curves, we obtain—

Discharge.		Charge.		Percentage working efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
82.6	161.3	86.2	190.5	95.8	84.7

*Fourth Rest.*—The cells, having been fully charged, were allowed to rest for 16 days. Curve 16 gives the values of P.D. obtained at the first discharge, and curve 17 the values of the P.D. obtained immediately afterwards in charging. Integrating the former curve, and comparing its area with the area of the charge curve (15) obtained just before the rest, we find—

First discharge after rest.		Last charge before rest.		Percentage efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
56.5	110.5	86.2	190.5	65.5	58

If, however, we compare the result of the first discharge after the rest with the first subsequent charge, shown in curve 17, we find—

First discharge after rest.		First charge after rest.		Percentage efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
56.5	110.5	71.1	158.3	79.6	69.6

The cells were now continuously, without intermission, charged with the normal current of 9 ampères, and discharged with 10; the discharge, as before, being automatically stopped when the P.D. per cell had fallen to 1.8 volts, and the charge when it had risen to 2.4 volts. The following give the successive times in hours and minutes in which the cycles were completed :—

First discharge after rest 5 h. 40 m.	First charge, 7 h. 54 m.
Second „ „ 7 h. 6 m.	Second „ 8 h. 30 m.
Third „ „ 7 h. 31 m.	Third „ 8 h. 51 m.
Fourth „ „ 7 h. 29 m.	Fourth „ 8 h. 52 m.
Fifth „ „ 7 h. 43 m.	Fifth „ 9 h. 17 m.
Sixth „ „ 8 h. 0 m.	Sixth „ 9 h. 24 m.
Seventh „ „ 8 h. 5 m.	Seventh „ 9 h. 17 m.
Eighth „ „ 7 h. 57 m.	Eighth „ 9 h. 20 m.

From the last three discharges and charges we see that the cells have arrived at a steady state, and curves 18 and 19 show the steady, or working, values of the P.D. for these three discharges and charges. Integrating the areas of these two sets of curves, we find—

Discharge.		Charge.		Percentage working efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
80	156.9	83.8	184.6	95.5	85

*Fifth Rest.*—The cells were now left charged for a further period of 16 days. Curve 20 gives the values of the P.D. obtained at the first discharge after the rest, and curve 21 the values of the P.D. obtained immediately afterwards in charging. Integrating the areas of these curves, we have—

First discharge after rest.		Last discharge before rest.		Percentage efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
53.3	104.1	83.8	184.6	63.6	56.4
		First charge after rest.			
		58.5	128.3	91.1	81.1

Continuous charging and discharging with the normal currents between the normal limits of P.D. per cell gave the following times for completing the cycles :—

First discharge after rest 5 h. 20 m.	First charge, 6 h. 30 m.
Second „ „ 6 h. 18 m.	Second „ 7 h. 29 m.
Third „ „ 6 h. 42 m.	Third „ 7 h. 59 m.
Fourth „ „ 6 h. 54 m.	Fourth „ 8 h. 19 m.
Fifth „ „ 7 h. 15 m.	Fifth „ 8 h. 20 m.
Sixth „ „ 7 h. 16 m.	Sixth „ 8 h. 30 m.
Seventh „ „ 7 h. 23 m.	Seventh „ 8 h. 41 m.
Eighth „ „ 7 h. 34 m.	Eighth „ 8 h. 44 m.
Ninth „ „ 7 h. 40 m.	Ninth „ 8 h. 47 m.

It was concluded from the times of the last three charges and discharges that the cells had acquired a steady state, and curves 22 and 23 show the time fall and the time rise of P.D. Integrating the areas of these curves, we have—

Discharge.		Charge.		Percentage working efficiency.	
Ampère-hours.	Watt-hours per cell.	Ampère-hours.	Watt-hours per cell.	Quantity.	Energy.
76	149.5	78.3	173.2	97.1	86.3

(To be continued.)

LEGAL.

**Stanley and Davies v. Milner and Co.**—This case came on for hearing at Manchester last week before Mr. Justice VAUGHAN WILLIAMS and a Common Jury.—The plaintiffs, who are engaged in business as electrical engineers, sought to recover from the defendants, who are bleachers and finishers at Pendlebury, £136 for goods sold and work done. Mr. Fleming appeared for the plaintiffs, and the defendants were represented by Mr. Yates. Counsel for the plaintiffs stated that, on the 6th of June, 1889, negotiations were commenced between the parties for the lighting of the defendants' works by electricity. On the 7th of August, a contract was made by the plaintiffs to do the necessary work. An installation consisting of 46 lamps was accordingly placed in the works, and the illumination was so complete that Mr. Milner expressed himself satisfied with it. When the plaintiffs' men had left the works, complaints were made by the defendants to the effect that the installation was working improperly. The plaintiffs went to see what was the matter, and made the necessary repairs. They, however, found that a man was in charge of the installation who knew nothing about it, and that the defendants' workpeople did not take due care of the machinery for producing the electricity. Under those circumstances it was natural that the installation should go wrong. The plaintiffs repaired a number of lamps which appeared to have been broken by negligent means, but eventually refused to undertake further supervision of the plant unless they received a proper order from the defendants. The installation only consisted of 46 lamps, and of these not more than eight had been the subject of complaint. The defendants had pleaded that the whole installation was useless to them, and refused to pay the amount claimed by the plaintiffs, with the exception of £42 10s., the price of an engine, which amount they had paid into court. Mr. Thomas Stanley, one of the plaintiffs, gave evidence bearing out the statement of counsel. In answer to Mr. Yates, he said that if acid vapours floated about the works and got inside the lamp holders they would corrode the metal. All the main branch wires were cased with wood, and he contended that the wires were fit for electric lighting purposes. He was not aware that electricity escaped to such an extent that no fire office would insure the works.

Other witnesses were called for the plaintiffs, whose evidence went to show that the installation worked satisfactorily when completed. The machinery, however, was not duly cared for, and the result was that after the plaintiffs had left the works the

plant began to work irregularly. Some of the wires also became corroded, owing to the acidulous vapours that floated about the works.

Counsel for the defence submitted that the contract with the plaintiffs was to fit a bleachworks with an electric installation—"the wire to be of the best insulation, and of the highest conductivity of copper." The work was to be done in the best possible manner, and to be fit for a bleachworks. It was admitted in the plaintiffs' case that the wire inserted was not "of the best insulation and the highest conductivity of copper." That was a material point, because the fact that corrosion ensued showed that the material could not have been of the highest kind, or that it was fitted in the best possible manner.

The JUDGE said that, on the contract as it stood, it was extremely doubtful whether the sellers of the machinery contracted to supply machinery suitable with reference to the peculiarities of bleachworks. The whole question of the case was whether the plaintiffs were bound to supply machinery suitable with reference to the peculiarities of bleachworks. He should ask the jury whether the machinery supplied was fitted for bleachworks generally. It was really common ground, and it was tolerably clear that the failure of the machinery was due to corrosion of the wires and holders, in consequence of the presence of steam and acidulous vapours. The whole question of the case was whether the plaintiffs were bound to supply machinery which should afford protection against these vapours.

Mr. H. MILNER, one of the defendants, said the process of bleaching carried on by the defendants was the ordinary one. The installation by the plaintiffs never worked satisfactorily, and occasionally paraffin lamps had to be resorted to.

Mr. E. W. COWAN, an electrical consulting engineer, said he had examined the electrical machinery at the defendants' works. The failure of the plant was due to corrosion of the fuse wire. The wire laid was not of "the best insulation and highest conductivity of copper." The corrosion of the fuse wire caused a leakage of electricity, and the firm in that case ran a risk of fire.

Mr. FAWCUS, manager for the Edison and Swan Company, considered the wire not only unfit for bleach-works, but altogether unsuitable for electric lighting.

The JUDGE said he proposed to ask the jury the following questions:—(1) Was the machinery delivered according to contract, apart from its suitability for user in bleachworks? (2) Was the machinery delivered according to contract, assuming that the plaintiffs contracted to supply machinery suitable for user in bleachworks? (3) Was the machinery wholly useless, or only defective? If only defective, at what sum did they assess the defect?

Mr. YATES said he thought it was assumed that the machinery was useless, otherwise he should have asked the two scientific gentlemen he had called whether it was absolutely bad.

Mr. FLEMING said the plaintiffs only complained of eight lamps out of 46 being defective.

The JUDGE remarked Mr. Yates was at liberty to recall one of his witnesses.

Mr. FAWCUS (re-examined) said he should not like to say that the machinery was useless, or to put any value upon it.

The JUDGE: What would be the most prudent thing for a man to do with that installation in your opinion? Would you take it out and get a new one, or alter it so as to get rid of the present defects?

Mr. FAWCUS: I should certainly take it out and get a new one. The present dynamo might be used again, but new wiring is absolutely essential.

Mr. FLEMING having addressed the jury on the evidence, The JUDGE summed up.

After a brief absence, the jury returned a verdict for the plaintiffs for the amount claimed, and judgment was entered accordingly.

**International Cable Company.**—The petition for the winding up of this company, which has been before the Court on several occasions, was resumed before Mr. Justice Stirling.

Mr. HASTINGS, Q.C. (with him Mr. Grosvenor Woods), said the petition was presented by a contributor upon the ground that the substratum of the company was gone, and after the case had been very fully argued in May last, his lordship came to the conclusion that it was not absolutely certain that the Portuguese concession, which was the substratum of the company, was gone, more especially as it was suggested that the Portuguese Government might have revived it, and accordingly directed the petition to stand over until to-day. An affidavit had been made by Mr. Rochs and Sir Alexander Armstrong on behalf of the company, but from this affidavit it was clear that the substratum was gone, and that there was no more chance of the concession being got now than there was of a gold mine being got by the company. What these gentlemen stated was this—that Senor Carilho, who seemed to be very friendly with everybody, including the Portuguese Government, had a great chance of getting a new concession between Lisbon and the Azores, and they also thought it was extremely probable that if he got it he would be ready to part with it to the company for a very moderate sum of money, and they were also sanguine that the necessary capital would be subscribed. Therefore, this affidavit clearly proved that the old concession was gone, and that the capital was absolutely insufficient for working either the old or new concession. Under these circumstances, he submitted that the petitioner was entitled to a winding up order.

The further hearing was adjourned until to-morrow.

## NEW PATENTS—1890.

10508. "Improvements in electrical railways and tramways." J. HOPKINSON. Dated July 7.

10515. "An improved connector for the electrodes and cells of primary and secondary electrical batteries." A. J. JARMAN. Dated July 7. (Complete.)

10527. "Improvements in magneto-voltaic and static electrodes." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10528. "Improvements in electric atomizers." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10529. "Improvements in pneumo-dynamometers." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10530. "Improvements in liquid electrodes." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10531. "Improvements in the healing electric static cup." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10532. "Improvements in electro-inhalers." E. S. D'ODIARDI and A. THOMPSON. Dated July 8.

10577. "Improvements in automatic electric fire alarm systems." P. JENSEN. (Communicated by the European Fire Service and Motor Co., United States.) Dated July 8. (Complete.)

10587. "Improvements in electric switch apparatus." P. KNOCH and M. PFEIFFER. Dated July 8.

10593. "Improvements in electric motor apparatus." S. C. C. CURRIE. Dated July 8. (Complete.)

19595. "Improvements in apparatus for measuring electrical energy." E. THOMSON. Dated July 8. (Complete.)

10640. "Improvements in sash fastenings and sash latch locks, and electric bell contact alarm, burglary preventer and detector." W. W. WILLMOTH. Dated July 9.

10646. "Improvements in apparatus for automatically controlling or maintaining electric circuits." M. H. KILGOUR. Dated July 9.

10712. "Improvements in electric lamp couplers or holders." A. E. NICHOLS. Dated July 10. (Complete.)

10714. "Improvements in and connected with electrical apparatus for recording the presence of watchmen, workmen, or others." W. LUCAS and T. A. GARRETT. Dated July 10.

10736. "Improvements in electric lamps for medical and surgical purposes." M. P. OUDIN and H. O. KRATZ-BOUSSAC. Dated July 10.

10740. "Improvements in incandescence bodies for electric glow lamps." SIEMENS BROTHERS & Co. (Communicated by Siemens and Halske, Germany.) Dated July 10.

10741. "Improvements in incandescence bodies for electric glow lamps." SIEMENS BROTHERS & Co. (Communicated by Siemens & Halske, Germany.) Dated July 10.

10742. "Improvements in incandescence bodies for electric glow lamps." SIEMENS BROTHERS & Co. (Communicated by Siemens and Halske, Germany.) Dated July 10.

10743. "Improvements in the means for effecting conducting connection between overhead conductors on electrical railways and tramways and the electrical apparatus on the vehicles." SIEMENS BROTHERS & Co. (Communicated by Siemens & Halske, Germany.) Dated July 10.

10765. "Improvements in means or devices for detecting electrical inductive effects." A. W. HEAVISIDE and E. C. JACKSON. Dated July 11.

10792. "A new or improved combined door knocker and electric bell." F. WILCOCKS. Dated July 11.

10801. "Automatic clock work apparatus for effecting cooking operations, the lighting of fires, and the like, also applicable for giving electric signals." J. J. GILBERT. Dated July 11.

10805. "Improvements in methods and apparatus for applying the power of electric motors, especially applicable to electric railways." B. J. B. MILLS. (Communicated by T. A. Edison, United States.) Dated July 11.

10806. "Improved underground conduit system for electrical distribution." B. J. B. MILLS. (Communicated by E. T. Greenfield, United States.) Dated July 11.

10857. "Improvements in metallic coverings for electric wires." J. M. MUNRO. Dated July 11.

10868. "Improvements in electricity meters." E. DE PASS. (Communicated by E. Marès, France.) Dated July 13. (Complete.)

10900. "An improved electric switch alarm." C. VANDERBILT. Dated July 12.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1889

6875. "An improved construction and mounting of the spring armature and hammer for electric bells and other like electrical instruments." J. C. WILLIAMSON. Dated April 24. 8d. Consists in mounting the armature on a spring (straight or curved) which may be of steel, brass, or other suitable metal, and which at its free end carries the hammer for an electric bell. 5 claims.

8958. "An electric meter." A. FRAGER. Dated May 29. 11d. Relates to an electric meter consisting of three principal parts or organs:—(1) an electro-dynamometer, which at every instant indicates the electric energy expended per second; (2) a clockwork which indicates the time during which the energy is expended; (3) a counter which registers the product of energy by time on suitable dials. 6 claims.

20261. "Improvements in electric semaphores for railways." F. STITZEL, C. WEINDEL, A. REUTLINGER, M. J. SCHWARTZ, J. H. EGGELHOFF, and J. KREIGER, all of the City of Louisville. Dated December 17. 8d. Has for its object to produce a semaphore which shall be sure and effective in operation. A further object is to so construct the apparatus that but little battery power will be required to operate it. A further object is to so construct a semaphore apparatus that when set the rattling of the parts caused by the jar of a passing train will not operate to release the mechanism. A further object is to construct a semaphore device in which some of the parts make contact with other parts with more or less pressure, so that when it is desired to release said parts one of them will be positively pushed from the other. A further object is to produce a signalling device actuated and controlled by the combined force of weights and electricity, and which shall be compact in construction and sensitive in operation. 14 claims.

20400. "Improvements in apparatus for obtaining a record of the movements of indicators by means of electricity." T. J. MURDAY. Dated December 18. 8d. Has for his object improvements in apparatus for obtaining, by means of electricity, a continuous record from a distance of the indications or movements of instruments or indicators, such as steam pressure gauges, anemometers, aneroid barometers and the like, which are provided with an index or pointer moving over a scale. 1 claim.

20911. "Improved battery plates for storage batteries." A. E. WOOLF. Dated December 31. 8d. Relates to particular methods of constructing the plates. 9 claims.

20971. "An electric exercising machine." O. IMRAY. (Communicated from abroad by the Electric Exercising Machine Company of America. Dated December 31. 8d. Relates to an exercising machine by which when used electric currents are conveyed through the body of the user, thereby obtaining simultaneously the therapeutic effects of the bodily exercise and the application of electricity. 10 claims.

## CORRESPONDENCE.

### Fire Office Rules.

In reply to Mr. J. B. Verity's letter in your last issue, asking what is to be done to meet the various requirements of the insurance companies, I should like to suggest that the best way to avoid trouble is to carry out all installations in accordance with the Phoenix Fire Office Rules, which are so well known and understood.

I do not think that any other office would object to work, if carried out in this way, as it is well known that the Phoenix rules are the most complete and also the strictest. Surely they cover all other rules, though the latter do in many cases differ, inasmuch as they are more lenient and often do not ask for such good material as the Phoenix, but I do not think an inspector would object on that score. I always carry out my contracts in this way, quite regardless whether Mr. Heaphy will inspect the work, or any other surveyor, and have never experienced any difficulties with the other offices.

It is, of course, a great misfortune that there is not a standard set of rules for contractors to work to, as endless trouble might thus be saved. I think the rules of the Institution of Electrical Engineers would have to be considerably revised before they could be accepted as a standard.

F. Geere How d.

July 20th, 1890.

### Electric Traction.

Having read an article in your REVIEW concerning myself, I shall be obliged by your permission to say a few words in reply.

You say that my work will be published in a few weeks' time. You would have been more exact had

you said that it had already been published at length in *La Lumière Electrique*, and that almost simultaneously a translation had appeared in the New York *Electrical World*. It has, in fact, been published in Brussels and Madrid as well.

Regarding my method, which I prefer (for Paris, be it understood) to the self-contained car and the electric locomotive, you quote the objections raised by a Parisian journal, that "it would present difficulties in practice owing to the length of the coach." The objection might as well have been taken to the horses, by which the length of the coach is increased some 4 metres, whereas my arrangement would only increase it by 2 metres or 2 m. 50.

You say it is a pity that my scheme is based upon estimates and not upon facts: allow me to disagree with you there.

In devising a practical scheme, which has no present existence (such as electric traction applied to the tramways of the General Omnibus Company of Paris), we are bound to make a forecast of the probable expense, and a detailed estimate of this sort can very well be made upon facts which have a separate existence elsewhere; and the exactness of the entire estimate may be perfect although all the details have as yet not been combined in a single scheme.

Thus if, for example, I estimate the salary of the head of a dépôt at 4,800 frs., that of an overseer at 3,600 frs., that of a workman at 1,800 &c., it is because we consequently meet with persons filling these offices on such salaries.

If I estimate the cost of a steam engine at 0.085 fr. per hour, it is because it is well known that under analogous conditions of power and of work in Paris, that is the average cost.

As regards the cost of plates and accumulators, you will admit that I am in a position to judge; and further, I will agree to deliver them to any amount under the conditions I have named.

You say I have taken no account of the conductors' wages, which is perfectly true, and would be equally true of the innumerable expenses which are incident to animal traction as well as electric traction, and which are of no interest in deciding the simple question of traction, and would be a useless complication of the estimate. What is important is the difference between the cost and the net profit of the two kinds of traction, and expenditure which is common and equal to both alike have no bearing on the question. As regards the gross expenditure, therefore, we need only consider the expenditure on plates and accumulators. Now, I read in the *Revue Industrielle* of the 5th July, an assertion by Mr. Frank Wynne, that in England it is not possible to obtain accumulators for electric traction capable of bearing more than 200 charges. Mr. F. King, on the other hand, mentions 450; whereas my calculation was 180 charges. You will, therefore, admit that there is no absolute agreement even in regard to facts; and that, at any rate, by taking the most unfavourable figure, my conclusions in favour of electric traction are more likely to be correct.

Finally, you challenge me to furnish data from a given line in Paris. If you will only take the trouble to look up the journal I have mentioned, you will see the following: "The service is yet too recent to offer any idea of the cost of maintenance of the accumulators." It would, therefore, be of no use for me to ask for these details.

I shall be obliged by your inserting the above remarks in an early number of the ELECTRICAL REVIEW, and beg to thank you in advance, &c.

Paul Gadot.

### A Correction.

At the commencement of line 10 in my letter last week about lubricating oils, instead of plaintiff company, it should read *defendant* company.

J. C. Richardson.

## THE POSTMASTER-GENERAL AND POST OFFICE MEETINGS.

IN connection with the discussion of the Post Office estimates, an interesting debate was opened up last week in the House of Commons, when a matter largely affecting the liberty of action of all sections of public officials coming under the control of the Postmaster-General was submitted to severe criticism.

Some time ago the Postmaster-General issued, what were termed, new regulations, under which those engaged in the departments under his control might hold public meetings—these regulations were spoken of as being a relaxation of an official order dated 1866.

From the surprise evinced publicly and officially at the discovery of this comparatively ancient document, and its subsequent amendment by the Postmaster-General, there can be but little doubt that thousands of those directly interested had never heard, or even dreamt of, such a regulation. The heads of departments, too, were in precisely the same state of happy ignorance, and the intelligent being who succeeded in resurrecting the almost unknown order of 1866 from some dusty, neglected, and probably all but forgotten official sarcophagus, will feel that he, at all events, deserves well of his Queen and his country.

The obsolescence of this practically unused tool was too palpable, however, to even a Postmaster-General, and though it was put before the Post Office departments in a sort of "this is what it could be" style, the amended order was adopted as the standard by which all future "staff" meetings would be gauged.

We have referred to the order of 1866 as practically unused. No instance has been quoted in which its application has been resorted to. The Postmaster-General, indeed, confessed that, to his surprise, its existence had been ignored; but we go further than this, and say its existence was unknown; and previous events prove this to be true. It cannot be said that it could not have been used in the past twenty years, for there have been several movements in various grades of

the Postal Service, notably, amongst postmen, sorters, sorting clerks, telegraph clerks, and savings bank clerks, and these movements, at all events, extended to as far back as 1872. In 1881 a strong agitation, fully justified by results, and which made its existence felt throughout the country, occurred in the telegraph service. Prof. Fawcett, the Postmaster-General at that time, did not restrict in any way a movement which, we believe we are correct in saying, he regarded, and even spoke of, as constitutional. Whatever was thought of the progress of the events by the higher departmental officials at that time, and, in some instances, their hostility was not disguised, it is a matter beyond dispute that free public meetings were not only general, but recognised as the legitimate channel for gaining public attention, and most people will fail to see why this should not be the case now. In 1881, the order of 1866 was conspicuous by its absence; and even if it still lingered in the minds of a few, which we doubt, it was looked on as obsolete and old-fashioned. Though the Postmaster-General holds strongly that he has acted in an equitable spirit to those under him, still, the questionable advantages conferred by what will be regarded by many as a fair specimen of official tinkering, do not seem to have won the hearts of those who are inclined to go into the subject, and few will be surprised at their non-conversion. At such meetings in future no one is to be present save those in the service—whatever their status may be. This seems to be specially aimed at those public men whose presence is so often a tower of strength to causes in which many of those interested expect and seek an outside stimulus. But this restriction is double edged. If it deprives one side of friends and councillors it does the same to the other. Will the Postmaster-General say, for instance, that the presence of two or three earnest and moderate members of Parliament, or even other public men, at some of the recent meetings in connection with the mismanaged postmen's movement would not have averted the unfortunate catastrophe which unwise and hasty action engendered? Would not their in-

fluence have held in check, for example, what has been aggressive and suicidal zeal on the part of an individual, or individuals, at the head of the Postmen's Union?

The telegraph clerks' movement, too, may afford another case in point. After conducting a series of meetings in 1889, some with the aid of members of Parliament whose moderate and rational councils have always prevailed, and some without, nothing being kept from the public Press, which is surely a reliable medium of information and discussion, they, too, were brought under the provisions of the Postmaster-General's amended order.

To them assuredly the position was most unpleasant, especially after their unfettered experiences of 1881, and it may have been felt that the Postmaster-General's regulations were more irksome than he had any intention of making them.

There can be no doubt that in many quarters this restriction is considered harsh and arbitrary, and though the Postmaster-General repudiates all such intentions we cannot say that, even with the majority of the House of Commons on his side, he has made out a good case; on the contrary, we question the wisdom and expediency of his action.

The Postmaster-General also requires a statement of the business to be discussed at public meetings, and sends an official reporter to take verbatim reports of all speeches and the names of the speakers. A number of meetings have been held under these conditions, and the Postmaster-General professes to be satisfied with the results of his innovation. His satisfaction, we imagine, is scarcely shared by his subordinates.

To a few meetings, indeed, he has not deemed it necessary to send the "official reporter," and the absence of this doubtful advantage has not led to anything more startling than an expression of surprise that the Postmaster-General should have broken his own rule.

The Postmaster-General also urges that he requires true accounts of what is said, so that grievances and complaints of all kinds may be thoroughly understood and properly considered. He may attain these ends by his plan, but we have heard from not a few in various departments that they would be delighted to have the Postmaster-General in person at their meetings, though they object naturally enough to the "official reporter."

This ingenious if not ingenuous explanation would lead many people to imagine that such a thing as a free public press had no existence in these islands, or if it did exist, that its power as an advocate and mediator was practically inert. Happily, its power needs no demonstrating. It is mighty in its fearless trinity of advocacy, mediation, and criticism.

It must be palpable to everyone that in the hands of officials antagonistic to public meetings, public discussion, and public sympathy, the Postmaster-General's regulations are capable of being used in a most despotic and tyrannical manner, under which officialism would become invested with an aggressive as well as a repressive power, a menace to the one side and a danger to the other. Public opinion would remedy these matters,

but this might not be done until individuals had suffered.

On the other hand, under a generous observance of, and a fair adherence to, those constitutional principles which the Postmaster-General has expressed himself so anxious to encourage, little if any sense of a loss of constitutional right would be felt by those who had substantial and practical questions to ventilate.

Nevertheless, the era of such Draconian rules has certainly passed away, and, under the circumstances, many will regret that the order of 1866 was not relegated for ever to that official obscurity under which it had enjoyed the advantages of nearly a quarter of a century's rest and peace, its bare existence apparently unsuspected by quite a number of Her Majesty's Postmasters-General.

---

#### Fire Rules and Regulations.

WE are sadly in want of a set of standard rules for fire risks which would prove acceptable both to insurance offices and electrical contractors. As neither the Phoenix rules nor those compiled by the Institution of Electrical Engineers satisfy the requirements, much uncertainty and considerable annoyance, to contractors particularly, result. Not long since a firm of electrical engineers notified to a fire office that a certain installation was about to be fitted up, and a request was also made for the office to inspect, if it was thought desirable, insurance being effected also with another company. In reply, a letter was received from the inspector, asking for particulars, samples of leads, and enquiring whether the work was being carried out in accordance with the rules of his office. The contractors sent the conductor specimens, and an intimation that the installation had been carried out in the usual manner. They did not wish to commit themselves to any given rules, lest anything occurred afterwards by which they, through a technical objection easily raised on behalf of the fire office, might be held liable. The next episode in this little comedy of errors was the receipt of a letter by the contractors which their own client had received from the fire-office. To their surprise the document commenced by informing the recipient that in consequence of the numerous fires from electricity that have occurred, and the liability of electricity to suddenly cause fire without the least warning in any part of the house where the conductors run, it would be readily understood that the fire office was particularly desirous of ascertaining what precautions had been adopted against danger. Moreover, it was stated that the only reason for troubling the gentleman to whom it was addressed was because the contractors had refused to give any information as to the manner in which the installation was carried out, an assertion which, on the face of the correspondence was, to put it mildly, a perversion of the truth. What the upshot of the business is we do not know, but the incident shows clearly that there is considerable friction between fire offices and contractors, and the sooner they can transact their mutual affairs on a basis suitable to both so much the better for the consumers of electrical energy, who do not desire to be troubled with the quarrels of those whom they engage to supply them. Furthermore, when a fire office asserts that there have been numerous fires from the use of the electric light, and that there is a liability to this

danger at any time and without warning, it becomes desirable in the public interest that these facts should be known without delay. Captain Shaw recently reported that the fires in London from electric lighting amounted to three only during the years 1888 and 1889. Either he is right and the fire office wrong, or there must have been many conflagrations from this cause in the provinces, of which we have never heard. However this may be, we think electrical contractors might with advantage agitate for a set of rules which would enable them to carry out their work on some tangible basis, and steer them clear of the whims or caprices of inspectors, who are too often in antagonism with each other's regulations.

Gas Works and Electric Lighting.

IN the REVIEW for July 11th we published an abstract of a paper, read by Mr. Arthur F. Guy, entitled "Shall Gas Undertakings supply Electricity? Yes." Mr. Guy, who seems to be a very young man, and was probably carried away by the enthusiasm of youth, argued that gas companies were favourably situated in all respects for undertaking the supply of electrical energy; but a perusal of the remarks made by Mr. Stewart, the President of the North British Association of Gas Managers, entirely dissipates this idea. That the latter gives the correct view of the situation is certain, but it would be interesting to our readers to see how Mr. Guy proposes to combat the matured reasoning of his more experienced antagonist.

Improvements in Arc Lamps.

IN our issue of March 14th we commented somewhat strongly on the highly-coloured statements which had come before our notice respecting the immense advantage of introducing a hydro-carbon vapour into the electric arc. We freely admitted that the light would be increased, but we doubted the practicability of the methods adopted to regulate the supply of hydro-carbon. Moreover, so far as the principle of the invention was concerned, we showed clearly enough that it was of many years standing. Our views were perfectly correct as the mechanism of the lamp then stood, but since that period Mr. Apps, the well-known scientific instrument maker, who has been indefatigably introducing improvements in rapid succession in the Saunderson arc lamp, appears to have overcome what then proved serious obstacles to its practical operation, in an entirely successful manner. The method of producing the extremely small supply of vapour necessary has now been reduced to a matter of the greatest simplicity, and credit is due to the inventor who gave Mr. Apps *carte blanche* to proceed as he pleased for the pertinacity with which he has stood to his guns in the face of innumerable difficulties. Accompanied by Mr. Apps a few nights since, we wended our way to a metropolitan railway station, where a Brockie-Pell lamp, fitted with Saunderson's carbons, had been for some weeks regularly working in series with a number of Brush arcs. Naturally, in the absence of proper apparatus, we were unable to compile any definite photometric data; but by roughly measured shadow tests and other simple means, we had little difficulty in perceiving that the light was much superior to that given by each of the others—at least half as much again. The cost of producing this extra luminosity, Mr. Apps informed us, does not exceed 6 per cent. on the price of ordinary carbons, and it is proposed to sup-

ply the hollow carbons with the hydro-carbon attachment, which are made to suit any lamp, to the trade generally, on the basis of a very small royalty on the market price. This is a wise course to pursue, and doubtless Mr. Saunderson will reap much more benefit from universally dealing with lamp makers than by the course of promoting a company to exploit and introduce his invention as an improved lamp, such as at one time seemed probable. His greatest sphere of operations, we imagine, will be found in America and in certain continental countries, for the development of arc lighting here is slow and tedious in the extreme.

State Control and Telephony.

OUR friend, the *Electrician*, is, to put it mildly, a trifle shaky in its political economy. Having advocated in the strongest terms the purchase of the telephones by the State, Mr. H. W. Fawcus has written, putting the truth before our contemporary in language pretty similar to what we used in our leading article a fortnight since. The *Electrician* now declares itself utterly opposed to Socialism, but qualifies the declaration with the remark that the position of the Post Office is no more one of State Socialism than is the War Office. Whether the monopoly of letter carrying and telegraphing by the State is justifiable need not be here considered, but there is no doubt that its existence illustrates a distinct phase of Socialism, while the position of the War Office is a very different matter. It is the function of the State to protect the citizens from foes abroad and friends at home if need be, to dispense justice and enforce rights between man and man, thus maintaining a condition of things under which individual enterprise may develop and secure its due reward. The War Office undertakes to deal with the foreign foe, but it is scarcely necessary that for the protection of individual interests at home the State should carry the citizens' letters, deliver their telegrams, or keep telephonic bureaux open. In fact, our contemporary fails like a good many others to distinguish between what the State ought to do and what it should let alone, between the duties for the performance of which it exists and the affairs with which it has no business. Though the *Electrician* declares loudly enough for "no Socialism," due to that extraordinary obliquity of vision which distorts political views generally, it sees nothing subversive of its principles in a letter-carrying monopoly, in State controlled telegraphy, in Government subsidies to newspapers, or in officially managed telephony. The principle of Individualism is approved, and as that of Socialism has been disavowed, it becomes convenient to call schemes essentially socialistic in their character and scope, by another name. So our contemporary regards the supply of electricity as a commercial undertaking, but the supply of telephonic facilities as a State affair. Given a political creed, it is always easy to find excuse for an infraction of its tenets should such infraction be thought for the time expedient.

License to the Mutual Telephone Company.

REFERRING to the projected telephonic competition at Manchester, our contemporary, in the same article to which we refer above, says:—"For our part we cannot help thinking that one of its first and chiefest difficulties will be to obtain the licence of the Postmaster-General." Would it surprise our contemporary to know that the license is already granted?

# EXPERIMENTAL PROOF OF HELMHOLTZ'S RELATION.

THE difference between the chemical and the electrical energy of a cell is equivalent to the product of the absolute temperature with the change in the difference of potential, with the change of temperature, or, in other words, with the temperature coefficient of the cell. This is the theory enunciated by Helmholtz some time ago. According to this hypothesis, if the chemical energy of any given cell is greater than its electrical energy, the temperature coefficient is negative; whilst, on the other hand, if the electrical energy of the cell is greater than its chemical energy, the temperature coefficient is positive.

It is evident, on considering this theory, that if the temperature coefficient can be ascertained, it may at once be determined whether the chemical energy of the cell is only partially converted into electrical energy or whether the electrical energy of the cell is in excess of its chemical energy.

Experiments to prove Helmholtz's relation between the secondary heat of a galvanic element and its temperature coefficient were undertaken a short time ago by H. Jahn, who afterwards published his results in a paper which may be read in Poggendorf's *Annalen der Physik und Chemie*, Series II, Vol. xxviii., page 491.

The cells examined by Jahn were silver and silver nitrate with lead and lead nitrate, and with copper and copper nitrate respectively. The solutions were made up to a strength represented by the following formula:—

when M' stands for the metal employed. NO<sub>3</sub> for the "nitrate" part of the salt, and H<sub>2</sub>O for water.

Jahn was successful in obtaining a number of exceedingly interesting results, of which we may briefly allude to certain that are typical.

The chemical heat of a galvanic element is obtained from the formula—

$$Q = W - a J (\Delta - J \sigma) t$$

in which the letters have the following significance.

W = The heat evolved in the cell.

a = The heat equivalent of unit of work.

J = The current intensity in amperes.

$\Delta - J \sigma$  = The difference of potential of the electrodes.

t = The duration of the experiment.

The value obtained from this formula for Q, the chemical heat of the galvanic element, agree closely with those obtained from thermo-chemical data.

If Q' stand for the current heat and S for the secondary heat, then the secondary heat is given by the equation—

$$S = Q - Q'$$

that is to say, the chemical heat, less the current heat, gives the secondary heat which is compared with that obtained by calculation from Helmholtz's relation.

Here are some specimens which illustrate this and at the same time show the accuracy of Jahn's experimental work:—

These investigations into the equivalence of chemical energy and current energy have been supplemented quite recently by F. Streintz who has contributed an excellent paper to Poggendorf's *Annalen der Physik und Chemie*, Series II., Vol. xxxviii., p. 514.

In this paper he discusses Helmholtz's theory, and gives the results of an elaborate series of experiments undertaken by himself, and especially calls attention to his experiments with a silver-mercury cell and its relation to temperature.

Streintz observed some time ago that a cell composed of the following elements—

has an electromotive difference of potential of zero at the ordinary temperature. This was not explained at the time, but he now finds that the phenomenon is due to the fact that a change from positive to negative takes place here in the temperature coefficient, and that this change takes place at a certain temperature, T<sub>0</sub>, at which the difference of potential, p<sub>0</sub>, is equal to zero.

Hence it follows that if a silver mercury cell be plunged into ice-cold water, the silver forms the positive pole, whereas when the element is transferred to hot water, the mercury forms the positive pole, and the silver becomes negative.

Streintz has used this interesting cell in testing the theory of Helmholtz, which is briefly enunciated at the commencement of this paper, and he finds that there is a perfect agreement between the theoretical deductions of Helmholtz and his own experimental results. For the numerical data we must refer our readers to the original paper.

## THE ELECTRIC LIGHT AT BOMBAY.

[FROM A CORRESPONDENT.]

THE late Municipal Commissioner of Bombay last year advertised for tenders for the electric lighting of the city. These advertisements appeared in the two Bombay dailies, in some of the leading English papers, and in some American journals. Five tenders were sent in, particulars of which have been inserted in the Bombay papers.

The first of these was from Siemens Brothers, of Berlin. This company offered to erect and supply for £40,000 a complete generating plant and system of underground leads adapted for 5,000 glow lamps, 16 candle-power, but excluding cost of opening up streets, house, and street lamp connections.

Crompton & Co. proposed two alternative schemes for arc and glow lights respectively. The former plan would comprise 41 arc lamps of 2,000 candle-power, at 80 yards apart, the machinery in duplicate, but the site and machine house to be supplied by the municipality. Their prices are stated in such a manner as not to be easily comparable with the tender of Siemens Brothers and Co.

Laing, Wharton and Down propose an arc light system, including 33 lights for the road from the Apollo Bunder to the Crawford Markets and 20 in the markets. The lights are to be each of 2,000 candle-power, and to be charged for at the rate of £32 a lamp annually for two years, £30 if for three years, and £29 if for seven years.

Ganz & Co., of Buda-Pest, offer to light those parts of the Crawford Markets where gas is now used, with 14 arc lamps and 32 glow lamps of 25 candle-power each. They offer also to light the road from Crawford Market to the Apollo Bunder, Church Gate Street, and Elphinstone Circle, with 144 glow lamps of 25 candle-power placed 164 feet apart on opposite sides of the road. In addition they would supply 32 arc lights and illuminate the Clock Tower. The present amount of light now given in the streets is 2,800 candle-power; their glow lamps alone would give 3,600 candle-power, and the arc lamps 12,800. The annual charge would be 80,000 Rs.

Finally, the Orient Electric Light Company proposed to light the markets and the streets above-mentioned (except from St. John's Church to Colaba point), for two years with 650 lights of 16 candle-power. Their charge would be 5 pice per light hourly.

At a meeting of the Standing Committee of the Municipal Corporation, held June 25th, it was agreed that the commissioner be requested to prepare a special report on these schemes, and that he be authorised to apply to Government for the services of an electrical engineer, and also to expend any sum not exceeding 1,000 Rs. in making any needed scientific enquiries.

### AN EXPERIMENTAL PROOF OF OHM'S LAW, PRECEDED BY A SHORT ACCOUNT OF THE DISCOVERY AND SUBSEQUENT VERI- FICATION OF THE LAW.\*

By Prof. ALFRED M. MAYER.

I PURPOSE giving in this paper a simple and direct experimental proof of Ohm's law ( $C = \frac{E}{R}$ ). Generally

a mere formal statement of this law, with illustrations, are given in text books on physics, and the student is left to infer that its truth is shown by the cumulative evidence given by the immense number of quantitative relations in electrical actions which the law associates, and by the experience that deductions made on the basis of this law agree in measure with the results of experiments. The latter fact is certainly one of the best proofs of the truth of the law; but, nevertheless, the relations between  $C$ ,  $E$  and  $R$  are not directly and simultaneously shown to be exactly expressed by

$C = \frac{E}{R}$ . It is true that some works give experiments to show this relation, but they are so difficult to perform by reason of the difficulty of maintaining constant  $C$ ,  $E$  and  $R$ , that the results of the experiments only approximate to those required by the law.

Ohm was led to the conception of this law by *assuming* that the flow of electricity in a voltaic circuit is similar to the flow of heat by conduction in a rod of indefinite extent. Also, his assumptions that the actions of two electrified particles are directly as their distance, and that the electricity is uniformly dense over each cross section of a conducting wire, were directly opposed to the laws and facts well established by Coulomb for statical electricity. It is not surprising that scientific men were slow in adopting the views and theory of Ohm. In his memoir (*Die galvanische Kette mathematisch bearbeitet* von Dr. G. S. Ohm: Berlin, 1827) he states:† "Three laws, of which the first expresses the mode of distribution of the electricity within one and the same body, the second the mode of dispersion of the electricity in the surrounding atmosphere, and the third the mode of appearance of the electricity at the place of contact of two heterogeneous bodies, form the basis of the entire memoir, and at the same time contain everything that does not lay claim to being completely established. The two latter are purely experimental laws; but the first, from its nature, is, at least, partly, theoretical.

"With regard to this first law, I have started from the supposition that the communication of the electricity from one particle takes place directly only to the one next to it, so that no immediate transition from that particle to any other situate at a greater distance occurs. The magnitude of the transition between two adjacent particles, under otherwise exactly similar circumstances, I have assumed as being proportional to the difference of the electric forces existing in the two particles; just as in the theory of heat, the transition

of caloric between two particles is regarded as proportional to the difference of their temperatures. It will thus be seen that I have deviated from the hitherto usual mode of considering molecular actions introduced by Laplace, and I trust the path I have struck into will recommend itself by its generality, simplicity, and clearness, as well as by the light it throws upon the character of former methods.

"With respect to the dispersion of electricity in the atmosphere, I have retained the law deduced from experiments by Coulomb, according to which, the loss of electricity in a body surrounded by air, in a given time, is in proportion to the force of the electricity, and to a coefficient dependent on the nature of the atmosphere. A simple comparison of the circumstances under which Coulomb performed his experiments, with those at present known respecting the propagation of electricity, showed, however, that in galvanic phenomena the influence of the atmosphere may almost always be disregarded. In Coulomb's experiments, for instance, the electricity driven to the surface of the body was engaged in its entire expanse in the process of dispersion in the atmosphere; while in the galvanic circuit the electricity almost constantly passes through the interior of the bodies, and consequently only the smallest portion can enter into mutual action with the air; so that in this case the dispersion can comparatively be but very inconsiderable. This consequence, deduced from the nature of the circumstances, is confirmed by experiment; in it lies the reason why the second law seldom comes into consideration.

"The mode in which electricity makes its appearance at the place of contact of two different bodies, or the electrical tension of these bodies, I have thus expressed:—When dissimilar bodies touch one another, they constantly maintain at the point of contact the same difference between their electroscopic forces (potentials).

"With the help of these three fundamental positions, the conditions to which the propagation of electricity in bodies of any kind and form is subjected may be stated. The form and treatment of the differential equations thus obtained are so similar to those given for the propagation of heat by Fourier and Poisson, that even if there existed no other reasons, we might with perfect justice draw the conclusion that there exists an intimate connection between both natural phenomena; and this relation of identity increases the further we pursue it. These researches belong to the most difficult in mathematics, and on that account can only gradually obtain general admission; it is therefore a fortunate chance that in a not unimportant part of the propagation of electricity, in consequence of its peculiar nature, those difficulties almost entirely disappear."

From these premises, and guided by results of experiments made by him and by Ritter, Erman, Jäger, Davy and Becquerel, he arrived at the following conditions as existing in a voltaic circuit.

1. In a homogeneous conductor, forming part of a voltaic circuit, the difference of the electric tensions at any two points of the conductor is proportional to their distance.

2. In different conductors forming part of a circuit, the difference of tensions at two points separated by an interval equal to the unit of length is in the inverse ratio of the section of the conductor and of its coefficient of conductivity. Hence, in different conductors, equal differences of tension correspond to lengths whose electric resistance is the same.

3. At the point of contact of two different conductors, there is a sudden variation of electric tension.

4. If  $A$  equals the sum of the electromotive forces,  $L$  the resistances,  $\lambda$  the resistance reckoned from a point,  $m$ , of the circuit to a point,  $p$ , when the tension is zero, the tension at the point,  $m$ , is given by the formula,

$$u = A \frac{\lambda}{L}.$$

Ohm eventually arrives at the formula  $S = \frac{A}{L}$ , which

\* American Journal of Science.

† See translation, published in Vol. II. of Taylor's Scientific Memoirs, p. 402. London, 1841.

expresses what is generally known as his law. Which formula, he says, "is generally true, and already reveals the equality of the force of the current at all points of the circuit; in other words, it may be thus expressed: The force of the current in a galvanic circuit is directly as the sum of all the tensions, and inversely as the entire reduced length of the circuit, bearing in mind that at present by reduced length is understood the sum of all the quotients obtained by dividing the actual lengths corresponding to the homogeneous parts by the product of the corresponding conductivities and sections."

The words "tension" (*Spannung*) and "electromotive force" used by Ohm are the equivalent of the word *potential*. He was the first to introduce this conception into the theory of the voltaic circuit and to the above words and to *current* and *resistance* he attached precise meanings and showed the relations existing between those quantities. The clear definitions Ohm gave of these terms marked a transition from vague ideas of "quantity" and "intensity" to the clear conceptions of potential, electromotive force, current and resistance. The word *energy* he also used with clear and accurate meaning, as is shown in the following statement: "That the decomposing force of the circuit is in direct proportion to the energy of the current, and, moreover, that it depends on a coefficient, to be derived from the nature of the constituent parts and their chemical equivalents." This was published in 1827, six years before Faraday's researches on electrolysis.

energy of a given current would be spent in this way, would require a far more perfect knowledge of the dynamical theory of bodies than we at present possess. It is only by experiments that we can determine the laws of processes of which we do not understand the dynamical theory."

Surely, if an experiment, that is easily made, shows the truth of a law of such theoretical and practical importance as that of Ohm, even if it is one restricted in its range of C, E, and R, but shows within its limita-

tions the relations  $C = \frac{E}{R}$  then it should be made by

all teachers of physics so that clear physical conceptions of those relations may be given to students. As those who have seen these experiments have deemed them worthy of being more generally known, I now publish an account of them.

In the diagram, fig. 1, the parts of the apparatus are shown, but not at their relative distances apart or in the proper proportions as to size. G is a low resistance Thomson galvanometer. At L is the condensing lens of a lime-light lantern, which is covered with a cap having a rectangular opening in it. Across the middle of this slit is a vertical wire. The scale of the galvanometer is at C, distant 165 cms. from the mirror of the galvanometer. The width of the divisions on this scale are 2.5 cms., and the lines are drawn 2.5 mms. in breadth, or  $\frac{1}{10}$ th the distance apart of the centres of the lines forming a unit of the scale. The scale is at such

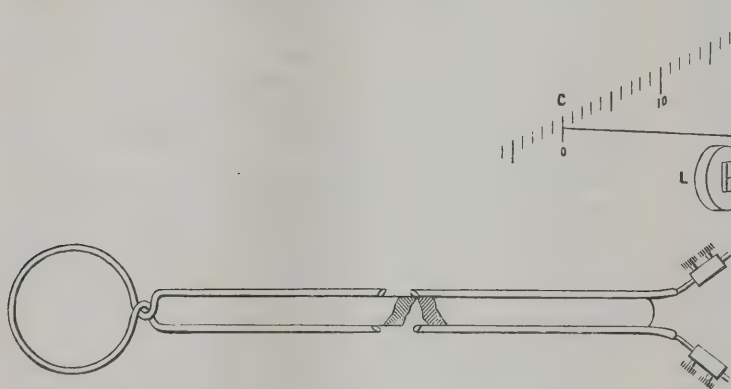

FIG. 1.

Neither Ohm nor his contemporaries were able to test the truth of the four statements given above as embodying Ohm's theory. It was reserved for Kohlrausch in 1849 to show by very ingenious and accurate experiments that Ohm's statements were true in mode and in measure. Kirchhoff\* and Quincke† applied with success Ohm's theory to the flow of electricity in thin conducting plates, or bodies of two dimensions, and the same was done by Smaassen,‡ not only in a plane but in bodies of three dimensions. The most remarkable confirmation of Ohm's law was made in 1876§ by experiments suggested by Maxwell and performed by Chrystal in the Cavendish Laboratory, Cambridge, "in which the testing of this law seems to have been carried to the limit of experimental resources."

Though Ohm's law has thus received such ample verification that it ranks with the best-established laws of nature, yet, as Maxwell says: "Ohm's law must, at least at present, be considered a purely empirical one. No attempt to deduce it from pure dynamical principles has as yet been successful. . . . The conduction of electricity through a resisting medium is a process in which part of the energy of an electric current, flowing in a definite direction, is spent in imparting to the molecules of the medium that irregular agitation which we call heat. To calculate from any hypothesis as to the molecular constitution of the medium at what rate the

distance from the galvanometer mirror that the image of the vertical slit just fits in the space of a scale unit, while the breadth of the image of the vertical wire is exactly equal to the breadth of a scale line. This arrangement gives the means of observing a deflection of the beam of light to  $\frac{1}{10}$ th and  $\frac{1}{20}$ th of a unit with quickness and accuracy.

The image of the slit is so bright and that of the wire so distinct that this method of observing deflections of the galvanometer may be used in broad daylight and the deflections may be read throughout the room.

An incandescent electric lamp with a part of its surface (behind the plane of its filament) silvered may replace the lime light. Thanks to this arrangement, I have been able during many years to make before my class electrical measurements, and to measure the radiation, reflection, refraction, diathermancy, and polarization of radiant heat.

At M is a magnet 25 cms. long and  $1\frac{1}{2}$  cms. in diameter. On this magnet slides a wooden disc. At R is a box containing 1, 2, and 3 ohms of resistance, made of coils of copper wire.

An insulated copper wire wound at its middle in a circle of one coil, or in a spiral of any number of coils is placed over the magnet and rests on the top of the wooden disc. Fig. 2 shows (one-half size) how this circle of one coil is made. It is bent around a wooden cylinder  $3\frac{1}{2}$  cms. in diameter, and then the free ends of wire are bent one-half turn on each other. The free lengths of the wire are then lashed to a light square rod of wood, as shown in figure. The wire and rod are then coated with shellac to cement them firmly to-

\* Pogg. Ann., t. lxiv., 1845, and t. lxvii., 1846.

† Pogg. Ann., t. xcvi., 1856.

‡ Pogg. Ann., t. lxiv., and t. lxxii.

§ Brit. Assoc. Rept., 1876, p. 36.

gether. Rings of spirals of 2, 3, 4, 5 and 6 coils are also made in the same manner, but the coils are in spiral, *i.e.*, in one plane, and are then cemented together with shellac between rings of thin card-board.

The length of wire forming each of these rings of spiral coils with the portion on its handle is one meter long.

The resistance of this length of wire, added to the resistance of the lengths between it and G and R, together with the resistance of the galvanometer is (for convenience) made one ohm.

It may be well here to speak of the adjustment of the galvanometer before describing the experiments, for I have noticed in some laboratories and lecture rooms galvanometers which are used not as they should be. I have noticed that the damping magnet formed a considerable angle with the plane of the coil. This was either because the medium plane of the coil was not in the magnetic meridian or because there was considerable torsion in the suspending thread.

In these galvanometers, or, at least, in mine, the median plane of the coil is placed parallel to the faces of the drum of the instrument. The plane of one of these faces is brought in the magnetic meridian of the room, which has been carefully drawn on the table under the vertical centre line of the galvanometer coil, by means of a long magnetic needle mounted like those used on plane tables. A line at right angles to this meridian is now drawn so that its point of intersection with the meridian line shall be exactly under the suspending thread of the mirror. In the vertical plane of the line, drawn at right angles to the meridian, is placed the vertical wire in the slit of the lantern, L, and also the zero line of the scale, C. The scale is parallel to the magnetic meridian. The galvanometer is now placed in the position given above, and the "directing magnet" removed to a distance. The image of the vertical wire at L will now be found on the zero of the scale if there is no torsion in the suspending thread. If it does not come to zero then the head of the rod to which the thread is attached is turned till image of wire coincides with zero of scale, and then the instrument is in adjustment, and it will give deflections as the tangents of the strength of current, or, in other words, the current strength will be directly as the readings on the scale. The magnet, M, is now placed so that it causes no movement of beam from the zero of the scale. The directing magnet, above the coil, is now so adjusted that the time of an oscillation of the magnet of the galvanometer is above five seconds.

The coil, E, over the magnet is put in the circuit of G and R. The wires between E and G and R are twisted and tied together, so that no induced current from the earth's magnetism may be caused by the motions of this part of the circuit. The image of wire is on zero of scale. Now on rapidly lifting the coil from around the magnet, a deflection is produced by the magneto-electric current thus generated. It is sufficient to know that the cause of this current is the quick lifting of the ring with one coil. If we replace this by a ring of two coils, we get twice the deflection, and rings of 3, 4, 5 and 6 coils give 3, 4, 5 and 6 times the deflection given by the ring with one coil. Adopting the conception of the lines of magnetic force, we say that the ring with one coil cuts a certain number of these lines, this cutting of the lines causes the current, and is the *electromotive force*. The ring with two coils makes two cuts of these same lines, or, cuts double the number of lines, the rings of 3, 4, 5 and 6 coils cut 3, 4, 5 and 6 times the number of lines, and hence give 3, 4, 5 and 6 times the electromotive force.

In these experiments the resistance of the circuit has remained constant. Now take the ring with 5 or 6 coils, and let us have one ohm as resistance of circuit. On lifting ring from magnet we get a certain deflection, which we may make exactly equal to a whole number of the units of the scale by sliding up or down the disc on the magnet. We now take out plug of resistance box, and make the resistance of the circuit two ohms. The deflection of the galvanometer magnet now becomes one-half of that of previous experiment, and

successively making the circuit with resistances of 3, 4, 5, 6 and 7 ohms, we get  $\frac{1}{3}$ rd,  $\frac{1}{4}$ th,  $\frac{1}{5}$ th,  $\frac{1}{6}$ th and  $\frac{1}{7}$ th of the deflection we got with one ohm in circuit.

When these experiments are made with the galvanometer in perfect adjustment, and with the precautions indicated below, the deflections arrive one after the other exactly as the law requires, thus showing, with sufficient precision for a lecture experiment, that the current is directly as the electromotive force, and inversely as the resistance. Indeed, generally, the closest scrutiny does not detect in the scale reading any departure from the law.

Certain precautions are, however, necessary in these experiments. The resistance outside the galvanometer must be of copper wire, for such is the wire of the galvanometer. Also, the whole of the apparatus must be put together the day before we make the experiments, and the room maintained at as constant a temperature as possible, so that the temperature of all parts of the apparatus is the same. The deflections should not exceed 15 divisions of the scale. Thus, if we start with 15 divisions of deflection for a resistance of one ohm we will get 7.5, 5, 3.75, 3, 2.5, and 2.143 deflections for resistances of circuit of 2, 3, 4, 5, 6 and 7 ohms; and if with a constant resistance we obtain a deflection of two divisions of scale with a ring of one coil, we will get deflections of 4, 6, 8, 10 and 12, with rings having 2, 3, 4, 5 and 6 coils.

It is necessary that the coils should be removed from the magnet *very quickly*, otherwise the deflections will not be as the law requires. In other words, the currents produced should be as instantaneous as can be obtained. Instead of rapidly removing the coils by the hand, I have sometimes lashed the coil and their handles to a spring-board with a hole in it, which went over the magnet. By a trigger this spring-board is released. We thus get the same velocity in lifting the coil in each experiment. We have found, however, that the hand of a good experimenter gives precise results. Sometimes I have sent the coil from the magnet by the blow of a stick delivered on the under side of the handle of the coil at its centre of percussion. There is no doubt some departure from the law in these experiments, for it is not possible in such experiments to obtain what is understood by instantaneous currents; and the damping of the magnet by the mirror acting on the air must come into play. Yet I have never seen any but insignificant and barely discernible departures from deflections required by the law. This follows from the small angles of deflections and low velocity of the motion of the galvanometer magnet in the experiments. It is also to be noticed that with a good magnet of the size stated, and with the galvanometer making one vibration in about five seconds, the coil with five turns passes over only 2 cms., or less, of end of magnet, in order that it shall give a deflection of 15 divisions of scale. It is evident that in these conditions a very short time is occupied in cutting the lines of force. If the maximum deflection used is 15 divisions of the scale, the actual angular deflection of the magnets and mirror amounts to only  $6^{\circ} 29'$ . Yet 15 divisions is quite a length on the scale, being equal to 37.5 cms. But these experiments may be as readily made with a ballistic galvanometer. Then the magnets and coils have to be of larger dimensions.

Experiments similar to those given have served to graduate galvanometers. We have here the means of sending definite amounts of currents through an ordinary galvanometer, and we may thus graduate its angular reading into their relative values in current. The damping of the galvanometer has, however, to be applied to the readings, and then the results may best be put in the form of a curve.

**Ozone.**—Mr. Ernst Fahrigh is the author of a paper in the *Chemical Trade Journal* for the 19th ult., entitled:—"The phosphorescence produced upon the first contact of ozone with certain fluids."

SOME POINTS ABOUT ALTERNATING  
CURRENTS.\*

By Prof. H. S. CARHART.

THE extensive use of alternating electric currents in the transmission of energy for the purpose of lighting and, to a limited extent, for power, necessitates a more general and exhaustive study of their action than formerly. Alternating current dynamos were early in the field, but their importance was not fully apprehended till after direct current apparatus had come into extensive use, not in fact till transmission at high voltages for incandescent lighting was made possible by the application to alternate current circuits of the inverted induction coil, called a transformer or converter. Since then alternating current apparatus has come rapidly to the front, and many eager investigators have made brilliant applications of it to practical purposes.

The phenomena of alternating currents are so totally different from those of direct currents that the electrician, whose conceptions touching electrical action have been largely derived from the application of Ohm's law, finds himself entirely unable to comprehend alternate working till his views have been modified by an attentive consideration of many new and perplexing facts.

The first of these facts is self-induction, which plays no part in direct current working except on opening or closing the circuit, but which is exalted to a plane of prime importance with alternate currents. It is to Prof. Joseph Henry that we owe the first clear apprehension and lucid explanation of this interesting phenomenon.

When a simple periodic E.M.F. is applied to a circuit so disposed that its different parts act inductively upon one another, then this E.M.F. does work, not simply against the ohmic or ordinary resistance of the conductor, by reason of which heat is generated, but also against a counter E.M.F. of its own creating. We are familiar with this division of work when power is transmitted to an electric motor. The impressed E.M.F. then meets with ohmic resistance generating heat, and with a counter E.M.F. in the motor, the armature of which revolves in a magnetic field, and, in virtue of this counter E.M.F., a part of the energy applied to the circuit is converted into mechanical work at the motor. Energy may thus be stored up by means of the counter E.M.F. arising in the motor.

In an analogous way when energy is applied to an alternating current circuit a part of it is lost in heat, and a part is alternately stored up in the magnetic field and again restored to the circuit. A small portion in practical working, probably a very small portion of the energy, is transmitted outward into space as electrodynamic waves with the velocity of light.

Such a circuit possesses two qualities, resistance and inductance. The former is a property by virtue of which the passage of a current is accompanied by the irreversible transformation of electric energy into heat; the latter is a property by virtue of which the passage of a current is accompanied by the absorption of energy in the form of a magnetic field. A part of the energy spent on the conductor is frittered away in irrecoverable heat, while the other part is associated with the circuit in a recoverable form. When the applied electromotive force diminishes or ceases altogether, this stored-up energy operates to carry the current forward. On account of self-induction a current appears to possess inertia, and so resists any change tending in either the direction of increase or of decrease. A flywheel, to which the turning force is applied to increase the angular velocity, is the mechanical analogue. Suppose no resistance except friction opposes the motion of the wheel. Then a part of the energy applied is converted into heat by friction, and a part is stored up in the motion of the wheel in a recoverable form, to be given out or restored when the turning force is withdrawn.

The effect of the inertia of the wheel is to resist the force tending to increase angular acceleration, and to keep up the motion of the wheel in the positive direction when the twisting force is withdrawn. So the inertia or self-induction of a current opposes any change either of increase or decrease in the current. It does more; it continues the current in the positive direction even after the impressed E.M.F. is withdrawn. If the force applied to the flywheel is gradually brought to a zero value, and is then gradually applied with increasing intensity in an opposite direction, the wheel will continue to turn in the positive sense after the force is applied in the negative sense. In other words, the phase of the wheel's motion lags behind that of the applied force, its zero occurring later than the zero of the force. During this period of motion in one direction and force applied in the other, the wheel is doing work on the agent applied to it. While the angular velocity of the wheel is increasing, the agent is doing work on the wheel, and the wheel is storing up energy.

In quite the same way when a simple periodic E.M.F. acts on an inductive circuit, the current lags behind the E.M.F. in phase. It reaches its maximum value after that of the impressed E.M.F. by an interval equal to the angle of lag expressed in time, and passes through its zero value at an equal interval of time later than the zero of E.M.F.

Hence there arises a second fact worthy of particular attention. The maximum current never reaches a value equal to the maximum E.M.F. divided by the resistance of the circuit, but falls short of this by a quantity depending upon the coefficient of self-induction and the rapidity of alternation. By the coefficient of self-induction is generally meant a constant,  $L$ , such that the product of this constant and the rate of increase or decrease of the current is the E.M.F. of self-induction. By Ohm's law the current equals the E.M.F. divided by the resistance; with alternating currents in an inductive circuit the maximum current equals the maximum E.M.F. divided by a quantity  $R^2 + L^2 p^2$ , in which  $R$  is ordinary resistance,  $L$  is the coefficient of self-induction or the inductance, and  $p$  equals  $\frac{2\pi}{T}$ ;  $T$  being the

period of alternation. The above expression is now often called impedance, or sometimes "apparent resistance."

Another noticeable difference between direct and alternating currents is that while with the former the rate of doing work is the product of the current and the E.M.F., or C.E., in the latter the mean activity is half the product of the maximum E.M.F., the maximum current and the cosine of the angle of lag, or  $\frac{1}{2} E C \cos \phi$ . When the angle of lag is zero the

activity is a maximum, or  $\frac{1}{2} E C$ . When the lag is  $90^\circ$ ,

or a quarter of a period, the activity is zero. Thus we have the remarkable combination of a periodic E.M.F. applied to a circuit, a periodic current flowing through it, and still no work done upon the circuit. "In this case there is no frictional dissipation of energy, but simply a give and take of energy between the magnetic field and the source of energy supplying the E.M.F." Thus the mains of an alternating circuit may be joined by a conductor of such high inductance, that approximately no energy will be transmitted across from main to main. Such is the case with a so-called "choking coil," or with a transformer when the secondary circuit is open.

Another point to which the electrician may profitably devote extended contemplation is the measurement of electrical quantities on alternating circuits. Several devices have been invented to serve as current integrators, notably those of Mr. Shallenberger and Elihu Thomson; but these are instruments serving rather for the commercial purposes of central station work than for scientific measurements of precision. The Siemens electro-dynamometer, when properly made of approximately non-inductive resistance, serves for the measure-

\* *Western Electrician*.

ment of the mean square of the current. It can be shown that the square root of this mean square is equal to the maximum value of a current, following the simple periodic law, divided by the square root of two.

To measure voltages the ordinary high resistance instruments will not answer at all, because they have high inductance. The Cardew voltmeter, which acts by the heat expansion of a straight wire, and some form of electrostatic instrument are the only device serving for the measurement of a simple periodic E.M.F. These again measure the mean square or the E.M.F., and this bears the same relation to the maximum E.M.F. as the mean square of the current bears to the maximum current. Hence the product of these two quantities equals  $\frac{E \cdot C}{2}$ . Neither of these instruments, however, gives

any indication touching the important angle of lag, and therefore they give no information respecting the electrical energy in the circuit, nor of the alternate storing and restoration of energy by means of the magnetic field. Dr. Louis Duncan has measured the efficiency of a transformer by means of a huge calorimeter. This method is undoubtedly accurate if carefully applied, but it is scarcely simple enough for general laboratory use. Much remains to be done in this direction.

Very much might be said in favour of electric lighting by alternating currents. Scientific tests have shown that the efficiency of such a system is not so high as its promoters would have us believe. Its great and undoubted advantage lies in its ability to transmit energy to a distance at high voltage, transforming to low voltage at the points where the energy is to be utilised in lighting. For high voltage means small conductors and economy in transmission, and low voltage at the glow lamp is a necessity.

#### FURTHER NOTES ON THE CAUSES OF DEATH BY ELECTRICITY.\*

By DR. EDWARD TATUM.

I NOTICE with pleasure that my results with dogs fully bear out the inference drawn by MM. Brouardel and Bourot† from their human autopsies, namely, that death from electricity is really initiated by cardiac arrest. I must say, however, in regard to autopsies in general, made after accidental electric shocks, that I do not think any (reasonable) number could be convincing as to the fundamental mode of death; for while their number might be large enough to include every lesion that electrical discharges could cause, yet, when several serious lesions appear in one autopsy, there is no way of knowing either the order in which they have been produced or, in fact, that any one of them has really been necessary to the fatal effect. I have, therefore, always thought that the only satisfactory mode of approaching the question would be one in which the action on different organs and functions could be discriminated in order of time.

It now seems certain that (with the animals and conditions that I have employed) cardiac arrest is invariably the real initiation of somatic death—no matter how strong the current may have been, nor what lesions of fatal dimensions may have been caused during the same application.

Permit me to review, very briefly, how I have reached this point, and how I have made an important further advance.

I started out with the object of finding the seat, and if possible the character, of the lesions by which electric currents might kill dogs.

I first eliminated the factor of general injury to muscles and nerves by showing that they could retain their physiological functions not only after the application of a current sufficient to produce somatic death,

but even after the direct passage through their substance of currents of more than tenfold the density that the fatal current had averaged in the neck. Neither was the blood discoverably changed by the direct application to isolated portions of it of equally dense currents.

I next eliminated the agency of the respiratory mechanism as a necessary factor by showing, on the one hand, that its functions might be retained and exercised even for several minutes after the heart had executed its last beat; while, on the other hand, I never succeeded in definitely arresting respiratory movements before the heart also had stopped. This I considered a most positive and important advance, for it eliminated from the inquiry everything except the central nervous system and the heart.

*Lesions* of the central nervous system were dropped from the account on the following grounds:—1. There is no cardiac centre in the central nervous system in the sense that there is a respiratory centre, such, namely, that the continuance of the heart's activity depends on the integrity of the centre, and ceases upon the destruction of the centre. 2. I have apparently passed, without fatal result, through the *euephalon* alone, considerably stronger currents than have traversed it when the chest has been included in a fatal circuit. 3. No increase in dose seems to be required, either with continuous or alternating currents, to arrest the heart after it has been separated from the central nervous system by the section of both pneumo-gastric nerves.

The only remaining modes that suggest themselves in which electric currents can arrest the action of the heart are three:—

1. By some action on the muscular substance of the heart, by which this muscle is directly deprived of the peculiar physiological property of originating its automatic beats.
2. By a stimulation to physiological activity of the nervous inhibitory mechanism of the heart, which has normally a restraining power over the heart.
3. A joint action, in which the two foregoing share the responsibility.

The part played by physiological inhibition is very clearly shown in the experimental results that I gave in the paper above-mentioned. I there contrasted the effects of battery currents (which deliver their electric energy with the least possible amount of nervous excitation) with rapidly alternating currents, which are far more efficient nerve excitants. The result was, as there stated, that the later currents proved also far more effective in arresting the heart.

That the *whole* of this difference in killing power is accounted for by the difference in nerve-exciting power is shown by the fact that, when the nervous mechanism was paralyzed in ether narcosis, the *difference* in efficiency between the two sorts of currents vanished, while the efficiency of the battery current was not reduced.

While with alternating currents the nerve-exciting property is responsible for at least more than half the result (since that is the lowest possible estimate of the fatal superiority of these currents), still this property is very probably not responsible for the whole of the mischief, since even in this case the currents must reach a certain very respectable density in order to kill.

With battery currents, however, it seems clear that at least nearly all the mischief is done directly to the heart muscle, since the different conditions under which they have been used have failed to show distinctly any factor that could be set down to nerve stimulation. A more direct and striking evidence, however, may perhaps be found in two experiments where I used dogs profoundly poisoned by *curare*.

This drug has the remarkable power of entirely emancipating from nervous influence (at least as far as experiment and inference can determine) all the *red* or *striated* muscular fibres in the body. When a dog is under its influence natural respiration is abolished together with all possibility of voluntary movement. This is not from any paralysis of the muscles, since they respond actively enough to direct electrical stimulation of their substance, but from the fact that they

\* *Electrical World*.

† "Annales d'hygiène publique et de médecine légale," April, 1885.

are cut off from the nervous direction, which they need in order to perform any natural action.

The heart muscle differs from all other red muscles in being what is called automatic; that is, it originates its own activity, and its contractions are not started by any nervous influence (though they are in the normal state unquestionably greatly modified by the nervous mechanism pertaining to the heart). The heart is, therefore, not directly stopped by curare; but, if artificial respiration is practised, it will go on beating regularly and vigorously until the poison is eliminated and the animal recovers.

Yet under this poison the animals succumbed to just about the same current density as when ether alone was used.

These, then, are the conclusions that I think I have legitimately established, for the animals and under the conditions mentioned:—

1. That, in death which follows an electric shock so quickly as to be called sudden, the heart is arrested as soon as, or sooner, than any other serious lesion of tissue or function is produced.

2. That, when a battery current is used, this cardiac arrest is brought about almost exclusively by some direct action upon the muscular substance of the heart, whereby its power of automatic contraction is lost.

3. That, when a rapidly alternating current is used, this cardiac arrest is brought about certainly very largely through the physiological cardio-inhibitory mechanism, although even here the direct action on the muscular substance is probably not without importance.

It is not yet known whether electrical currents, applied as I have described, produce a discoverable histological change in the heart. I have therefore not ventured to formulate the physical process by which the heart muscle is caused to lose its distinctive physiological functions. Perhaps that will have to be left to electricians. Probably the complete explanation—since it involves the as yet undefined relation which subsists between the physical and physiological properties of living matter—is yet a great way off. I am not without hopes, however, of being able to throw additional interesting physiological light upon the matter.

### PROF. LODGE'S COMMUNICATION ON "ALTERNATIVE PATH" EXPERIMENTS.

By S. ALFRED VARLEY.

THOSE who regard language as an instrument for word fencing will possibly find much to admire in the communication of Prof. Lodge that appeared in the last issue of the ELECTRICAL REVIEW.

Prof. Lodge does not condescend to reason; he speaks from an elevated pulpit, and seems to expect *our* ignorance to accept unquestioned the utterances of *superior* wisdom. At the same time, with the true instinct of an able artist, he delicately veils and tones down, with learned phrases, what, if only analysed, will be found to be little more than *ipse dixit*. I fear that I myself too often run into an opposite extreme, and tear to tatters what I am discussing by an over-anxiety to give a reason for everything; but I do my best to express myself in common-sense, understandable language; and those who read to learn will give me the credit, I think, of having seriously thought out what I venture to write about.

Now, in the journalistic correspondence which has occasionally occurred between Prof. Lodge and myself, he has never condescended to reason, and he seldom speaks from a level platform; the consequence is I cannot get into touch with him, and, from no fault of my own, I become forced into a more or less antagonistic attitude. Circumstances, combined with traditions, have tended to make me unconventional; I do not, therefore, fit properly into either the square holes or the

round holes society delights in, and every-day experience teaches me that not to be of a shape recognised by orthodox Cults is the unpardonable sin which can never be forgiven.

Prof. Lodge has, however, in his last communication shifted his ground a little, and I am thankful for small mercies. He *now* tells us that the spark observed at B is a derived spark. I agree with him that it is a derived spark, and I venture to say it is derived from the demagnetisation of the metallic path, and that it represents the percentage of energy transformed into magnetism in overcoming inertia, and which becomes temporarily occluded in the path, at the time the Leyden jar discharge is occurring.\* Now, having reached this stage, I find myself in a position to connect in an intelligible manner the spark at B with the inertia phenomena of *all* closed electric circuits, and what I observe both in galvanic as well as in dynamo circuits helps me to understand what happens when a Leyden jar discharge takes place through a metal path; and, further, as all knowledge reacts I have been able to clear up in my own mind certain difficulties in connection with the transmission of rapid alternations through conductors by studying what is observed when Leyden jars are discharged through metal paths.

Now, I dare venture to assert that neither Sir William Thomson nor Prof. Lodge will take upon themselves to say, in clear unambiguous language, that I am wrong in attributing the spark seen at B to current developed in the conductor during the act of demagnetisation, and in saying, as I do, that this spark arises simply from the completion of the circuit through the short air space that separates the metallically disconnected ends of the wire loop; but at the same time, if the truth be told, these two distinguished physicists would, I believe, do almost anything rather than admit the soundness of my conclusions, for to do so would be tantamount to admitting that I have successfully stormed an important stronghold of the newer theory.

Prof. Lodge says in his communication that the current of a Leyden jar is very strong whilst it lasts, but he gives no reasons why it is so, and in such matters as these the writings of Prof. Lodge and those of mine contrast very strongly; what he has put forward simply as a statement I have demonstrated, and I believe I am the only physicist who has ever undertaken the task of doing so. I have shown the connection that exists between ordinary Leyden jars, decomposition cells, plating baths, storage batteries, and voltaic cells, and I have pointed out that a charged Leyden jar is fairly comparable to a voltaic couple whose internal resistance approaches the infinitely great, and yet, for reasons developed in my articles, a Leyden jar discharge comports itself during an infinitely short interval of time as a voltaic cell whose internal resistance approaches the infinitely small. Men such as Faraday considered themselves to be simply students somewhat older in experience than their pupils, and their efforts were directed to setting their pupils thinking; but all this has been changed since certain mathematical physicists have claimed to be the authorities in electrical science. In place of reasoning, we have authoritative statements from scientific gods, and it is considered the rankest of heresy to question in any way the sensational utterances they from time to time thunder forth.

Now, my contention is that I have fairly analysed Prof. Lodge's so-called alternative path experiments; and I say that these experiments performed by himself demonstrate, as clearly as experiment can demonstrate, a scientific fact that Leyden jar discharges pass through the mass of a conductor. I further say, as I have already stated in my criticism of Sir William Thomson's paper, that what was observed when a cold cylindric iron frame, forming two paths for the alternations to pass through, was placed in the electric welder, did not suggest in *any way* a crowding of currents in the outer skins.

\* Reasons have been given at length in the course of the articles, and I have connected, by *consecutive* reasoning, all that I have published.

The communication of Prof. Lodge, published in *Industry*, has reference to my criticism of Sir W. Thomson's paper, but he passes wholly unnoticed the experiment I laid the most stress upon, as bearing more directly on the matter at issue, viz., the crowding of transient currents in the outer skins of conductors; and now Prof. Lodge expresses surprise at my taking exception to his having done so. In my articles I have analysed self-induction, and I have pointed out that on the assumption that my explanation is the true one, the inertia resistance of iron should become reduced after a red-hot temperature has been reached. I believe I am right in saying that no one but myself has hitherto given thought to this matter, and I have not yet had an opportunity of verifying it. Prof. Lodge *now* says *it is so*, no reasons are given, and I am not credited with the suggestion, but the giving me any scientific credit is what he and those brother professors of his, who not so very long ago opposed me in the law courts, are evidently very unwilling to do. Sir William Thomson, in the Court of Sessions, Edinburgh, took credit to himself for having become possessed of a shunt machine in 1880. He said that next to nothing was known of such machines at that period, and the burden of the song sung by the three professors was that as *they themselves* knew very little indeed about shunt machines even in 1880, *how was it possible* for Mr. Varley to design an advance on such machines in 1876.

It is no good pummelling straw, as Prof. Lodge remarks, and the leading horses to a stream if they do not desire to drink is about as useless. The fact that the ELECTRICAL REVIEW, in which the communication of Prof. Lodge appears, also contains the judgment lately given at the Court of Appeal at Edinburgh in the compound winding case, I hail none the less that it is purely accidental. My claims as a discoverer, which certain of our mathematical physicists have been doing their very best to ignore and to spirit away, have now been triumphantly sustained in two law courts. The judgment given in the Court of Sessions declared the evidence of certain highly-distinguished professors to be *neither* reasonable *nor* fair. The Court of Appeal has confirmed this judgment and expressed its surprise that a number of able and distinguished men "*should have been persuaded*" to give the evidence they did.

I have no desire to prolong this discussion. I shall repeat, as soon as I am able, the accidental experiment of Lord Armstrong, to which Sir William Thomson has imparted so much importance; but I think it quite possible that in the mean time we may have promulgated some more of what Prof. Lodge has so happily termed "unique corrections of formulæ."

## GAS WORKS AND ELECTRIC LIGHTING.

AT the annual meeting of the North British Association of Gas Managers, held at Perth last week, Mr. S. Stewart, in the course of his presidential address, said:—Having had the experience of supplying a section of Greenock with the electric light for a couple of years, I am able to speak somewhat confidently of the possible results of gasworks furnishing electric lighting. In Greenock, I may explain, we fitted up two dynamos, each equal to 100 incandescent lamps of 20 candle-power; and they were driven by a turbine water-wheel and gearing. Only one dynamo was run at a time; but both could have been worked if there had been a demand for the light. The plant was erected on ground belonging to the Water Trust some two miles from gasworks; and it was complete in all respects and provided with necessary testing apparatus. Some 25 incandescent lamps were employed in the streets—being put into the ordinary gas lanterns; and part of a sugar refinery was fitted up with 85 incandescent and two arc lamps. The whole of the mains and cables were carefully laid under skilled supervision, and worked with entire satisfac-

tion. During summer only one man was employed; but in the winter months another was taken on during the daytime, renewing and repairing the lamps, &c. Something like 1,000 yards of cable and 2,500 yards of wires were laid, including branch services to lamps, all put underground. The wires were double lead-covered, having high insulation, safety fuses, and distributing boxes. The district lighted outside the Water Trust ground was about 300 yards long by 100 yards wide. The total outlay on plant was £1,630; wages and working expenses came to about £150 per annum, exclusive of interest, depreciation, cost of supervision, and power. Had these been included, as in the case of gas supply, the expenditure would have been three times this amount. The sugar refinery was fitted up by the proprietor at a cost of upwards of £200 for the 85 incandescent and the two arc lamps. They paid the Gas Trust about £100 per annum for the supply of electricity, and 10s. per week to a man for looking after their lights. The expenses for one year, as estimated by the proprietor—including 5 per cent. on the outlay for wires and lamps, the renewal of the lamps and carbons, the payment to the Gas Trust, wages, &c.—amounted to £175; while their gas account for the portion of refinery lighted by electricity came to about £125. Finding, after a second year's experience, that their expenses were increasing, they decided to give it up and return to gas lighting. The Greenock Police Board, objecting to go on incurring an annual outlay for the few remaining lamps, stopped the experiment. If they could have induced parties to fit up a number of lamps equal to the full power of the dynamos and plant, their yearly expenditure would not have been proportionately increased; that is to say, supposing consumers fitted up the plant within their premises, and maintained it and attended to the renewal of the lamps. It is evident that the electric light cannot be supplied at anything like the cost of gas. Gas is the light of all classes of consumers; but the electric light, from its excessive cost, can only be the luxury of the rich.

As to the advisability of gas companies furnishing the electric light, it must be borne in mind that, from the expensive nature of the plant required, the capital necessary to supply a whole town would be so great as to prevent this being done; and all that an electric light company would do would be to select those parts of a town where there were shopkeepers willing to use it for advertising purposes, or whose stocks were such as would be injured by the products of combustion or the heat of gas, or where there were wealthy people willing to have the light for the novelty of the thing. Where gas is sold as cheaply as it is in most towns, there is no risk of the general adoption of the electric light. The introduction of the light must be so gradual that the natural increase in the consumption of gas which takes place in most towns would prevent its effect on the demand for the older illuminant being injuriously felt.

There is no part of a gasworks plant that can be utilised for the production or supply of electricity. The cost of laying cables from a gasworks to the locality proposed to be supplied would, in most cases, be so large that it would be necessary to erect plant in the immediate neighbourhood of the district. If a gas company were to take in hand the supply of the electric light it would necessitate putting capital into a new business having special plant and skilled labour, and supervision entirely different from a gas business. In order to make it pay active competition with the gas business would be needed; and one need hardly add that this can scarcely be done by those who find it requires all their energies to make gasworks pay, and at the same time provide a cheap and efficient light. In my opinion the supply of electricity should be left in the hands of those companies who specially take in hand such work, and gas companies should no more trouble themselves with it than they would with the supply of oil to those who prefer to burn this illuminant instead of gas—oil being a much more active competitor than electricity.

## EDINBURGH EXHIBITION.

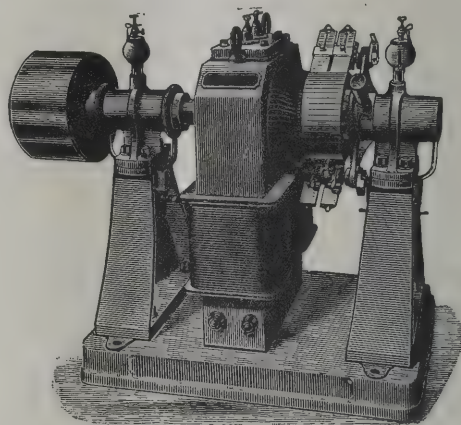

(Continued from page 41.)

*French Electrical Court.*—The interesting collection of exhibits from the Paris Exhibition, for which the French Electrical Court was specially erected, was open for inspection for the first time on the 10th July, and is now almost complete. One side of the building is wholly occupied by the exhibit of the Société Générale des Téléphones, consisting of a very fine collection of instruments, cables, and exchange switchboards. The Administration des Postes et Télégraphes also contributes a number of instruments and specimens of the different cables under its jurisdiction. The Northern of France Railway Company have laid down rails upon which is shown the manner of working railway points electrically, and they also exhibit an electrical capstan for working waggons and turntables. M. Clemancon shows his distribution boards and other specialities for theatres, as fitted by him in five of the Paris houses. There is also to be seen here a section of the Canalisation Electrique Crompton. The Société Cance show a variety of arc lamps ranging from 50 ampères to six, as well as a number of switchboards. The Cance lamps are also to be seen lighting the stand of Messrs. Prentice, Napier & Co. (No. 30). Messrs. Cauderay & Frager have a number of Frager's patent electricity meters suited to various requirements. M. J. O. Mouchel is an exhibitor of his high conductivity copper wire already made well-known in this country by his agents Messrs. Davis and Timmins. Amongst the other exhibitors are Ch. Mildé (bells, indicators, telephones), Richard Frères (electrical and other self-recording scientific instruments), Société Gramme (dynamo, cables), Sautter-Lemonnier (search light).

*Telfer Railway.*—As stated in a former issue this line was opened on the occasion of the visit of the Lord Mayor of London last month. It has been constructed by the Electrical Engineering Corporation (not the Electric Construction Corporation as erroneously printed in our former reference). There are now two trains running, each consisting of 3 carriages, and each carriage is constructed to hold six persons. On the occasion of the visit of the Institution the electric

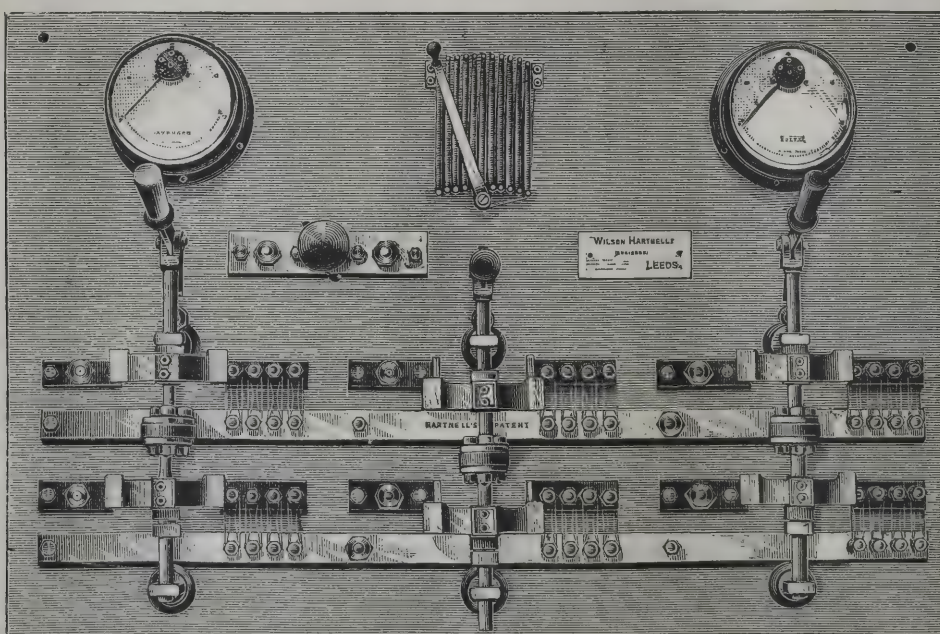

fitted with Hartnell's patent automatic expansion gear. The machine gives 110 volts and 163 ampères at 960 revolutions.

The magnets are made of the softest annealed wrought iron planed all over, and the spindle is  $2\frac{1}{2}$  inches in diameter, running in bearings of ample length. The commutator is exceptionally large and specially suitable for continuous running. The brush adjustments are novel and very convenient. This machine lights up the stand by some 30 16-C.P. lamps and 6 of 100 C.P. each. It also lights up two adjoining stands by an additional 140 lamps.

It also supplies current to a second dynamo or motor which is placed alongside. The output of this latter as a dynamo is 110 volts, 109 ampères at 1,000 revolutions. The current is taken from the dynamo to a distributing switchboard placed on the right hand side against the wooden partition. This switchboard comprises three main switches, Hartnell's patent compound multiple brush contacts, each intended for about 120 to 140 ampères. It is fitted with voltmeter and variable regulator together with ammeter and short circuit plug. This board is so arranged that any one of three dynamos can be put on to any one of three circuits, but the switches are so arranged that it is impossible for an unskilled man to short circuit one dynamo with another.

On the other side is placed a motor switchboard as

railway on the overhead conductor system, in course of construction by the same Corporation, was not ready for business, but it is now running.

No. 70.—Mr. Wilson Hartnell shows one of his latest type dynamos of 18,000 watts, driven by a horizontal steam engine, of Marshall, Sons and Co.,

used in the transmission of power. Both these boards are of the highest class of work and the principle is one which cannot but commend itself to the trade generally. We illustrate a three circuit board made on the same principle as the switchboards actually shown. In this case the installation is composed

of one dynamo only, and the circuits have about 120 ampères on each.

No. 43a.—*Smythe and Payne, Glasgow.*—This exhibit contains specimens of electrical fittings manufactured by Messrs. Fowler, Lancaster & Co., of Birmingham, for whom Messrs. Smythe and Payne are agents in Scotland. There are removable fuses, double and single pole, where the fuse is attached to a short bar of porcelain which can be lifted in and out of the clips which form the contacts, also wall connectors, ceiling roses, switches of different patterns, fuse boxes, bell pushes, &c., and specimens of Messrs. Smythe and Payne's new attachment cut-outs.

In this cut-out the heating effect of the current is employed without the necessary fusing of a wire, the device consisting of a mechanical contrivance for breaking the circuit controlled by a spring weight or other force, and held in check by a cord passed round a bare conductor carrying the current. This cord is made of a material that is readily charred or rendered brittle by the action of heat, so that when the conductor round which it is passed becomes heated by an excess of current this attachment cord gives way, allowing the mechanical contrivance to come into action and break the circuit.

As will readily be seen there is hardly any limit to the different patterns and designs in which this cut-out can be made. A few of them are shown in the figs. 1, 2 and 3, taken from photographs of those exhibited.

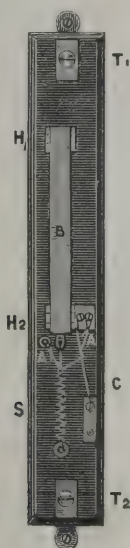

FIG. 1

In fig. 1, which is a narrow or beading pattern, suitable for branch circuits, the current enters at  $T_1$ , passes by the contact holder,  $H_1$ , along the bar,  $B$ , to the holder,  $H_2$ , thence along the conductor,  $C$ , and out at

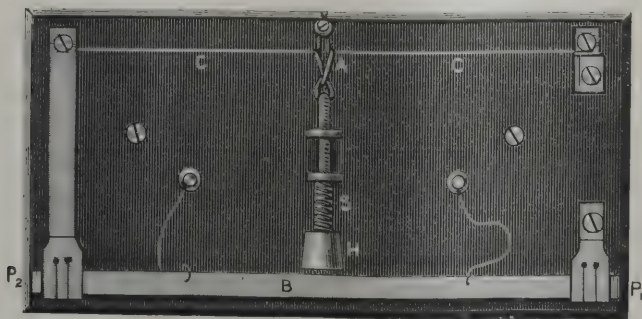

FIG. 2.

the terminal,  $T_2$ . The attachment cord,  $A, A$ , is passed round the conductor,  $C$ , and holds in check the spring,  $S$ ; when it is burnt through by the heating of the conductor it allows the spring to come into action and pull out

the bar,  $B$ , from the contacts,  $H_1$  and  $H_2$ , thus breaking the circuit.

In fig. 2 the contact bar,  $B$ , is knocked out by the hammer,  $H$ , when there is an excess of current. The hammer is held up by the cord,  $A$ , attached to a peg and passed round the conductor,  $C$ ; when the cord is charred by the heating of the wire the hammer descends under the action of the spring,  $S$ , and knocks out the bar from the contact holders,  $P_1$  and  $P_2$ .

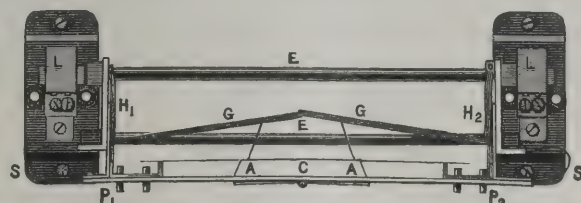

FIG. 3.

In fig. 3 is shown a special form of toggle pattern where the holders are held together by two ebonite rods,  $E, E$ , and fitted into spring clips,  $L, L$ , fastened to insulators on the wall. The cut-out can then be removed without touching any of the metal parts, and another one ready fitted with a cord immediately inserted in its place, or the cord renewed and the same one replaced; this form is suitable for a main cut-out on a high potential circuit. This pattern, like most of the others, can be fitted with small hooks on the toggles and bar, so that cords can be kept ready tied for insertion in the cut-out immediately after one has given way.

The cut-outs are also made with mercury cups, into which a metal bar dips and makes contact in the usual way; this bar is secured to a lever controlled by a spring or weight at one end, and held down by an attachment cord passed round a conductor carrying the current into the cups. When this cord is charred and gives way the spring, or weight, tilts up the lever arm lifting the contact bar out of the cups.

The device is also applied to switches themselves, so as to do away with the necessity of a separate cut-out. Almost any form of switch can be thus rendered automatic, so as to cut off the current if the latter becomes excessive.

After numerous experiments it was found that a gut or horsehair cord made the best attachment. Other materials were tried, including jute, flax, hemp, silk, leather, cotton, &c. The materials prepared to resist the action of water and used for fishing lines were also found to make good attachments. As the gut cords are stronger for their size than the majority of others, they are more suited to stand the constant strain of a spring or weight.

As the wire does not fuse, it will be seen that the same wire can be used over and over again, provided that the cut-out goes off with the same current each time; repeated experiments have found this to be the case, the wire can thus be permanently soldered down on to the switch or cut-out, thus avoiding two screwed contacts.

A platinum wire forms the best conductor, as it does not oxidise, and since it can be used permanently, the disadvantage of its expense is to a great extent overcome.

Where the lead consists of more than one strand, one or more of the strands can be removed, and the remaining ones fastened down to the cut-out to form the conductor, thus doing away with another screw contact, and avoiding the necessity of a separate wire for the cut-out; even a single wire can be thus employed by filing away some of the conductor where the cord passes round it so as to allow that part to become heated before the other parts of the circuit.

In all the experiments conducted, the cord was never seen to catch fire, even when the wire reached redness before the cord was burnt through, as was the case where some fine wires were tried in connection with coarse strings.

The advantages of this form of cut-out and combination switch are briefly as follows :—

It does not require the wire to be renewed every time the cut-out goes off; this renders it useful for ship lighting where string or tackle of some kind is always procurable, which is not the case with fuse wire of the exact size required.

A cord is a simple thing which can be tied by anyone. A considerable number of screwed contacts are done away with, especially where the lead itself is employed.

White hot wires with sputtering of molten metal is done away with. There is less chance of a wire being inserted, which is too large or too small, thus altering the "go off" point of the cut-out.

### EXPERT TESTIMONY AGAIN.

REPORTS on the working of electric tramways are always interesting and serve a useful purpose when drawn up by experts who are thoroughly acquainted with the subject. Two things are essential for the purpose of arriving at a logical conclusion as to whether a new system is as good as, or better than anything that has been done before in a given direction, viz.: Practical experience, and a knowledge of what has been achieved by predecessors. Sometimes an "expert" has either not the time to make himself acquainted with the state of the Art, or the remuneration is not sufficient to allow of the necessary sacrifice of time; under such circumstances it is prudent to refrain from making comparisons. Last week we published a report on the Lineff system, written by Mr. Kapp, who is a great authority on dynamos and transformers, but who, unfortunately, displays some lack of understanding in matters appertaining to electric traction. Mr. Kapp has evidently had no experience in this line, nor does he seem to be acquainted with the statistics published in papers read before scientific societies, particularly those of A. Siemens, Captain Douglas Galton, A. Reckenzaun, F. Sprague, Dr. Bell, Dr. E. Hopkinson, O. T. Crosby, and others. From these he might have learnt a good deal about the energy required for propelling tram-cars; this, with well-constructed appliances, amounts to between 5 and 8 H.P. on each car of the ordinary pattern; but at the generating station, from 10 to 16 H.P. is necessary for successful operation, and it is the same whether overhead conductors, underground conductors, or storage batteries are used. Referring to "economy of working," Mr. Kapp states in his report that: "to propel the same car by storage batteries would require an additional weight of 3 to 4 tons, at an expenditure of about 12 horse-power. Making due allowance for loss of power in charging and discharging cells, I find that the total amount of steam power required at the station would, with storage cars, be about double that required by the Lineff system." We should like to know where, and how, Mr. Kapp learnt that 3 to 4 tons of cells are necessary, for, as a rule, about half this weight is used; also, how he ascertained that storage cars require double the steam power? Surely the toy line, 75 yards long, constructed by Mr. Lineff, did not reveal such data, for the Lineff system certainly does not contain conductors of infinitely small resistance, nor does it remove the effects of gradients, and, least of all, does it exclude the possibility of leakage; thus the *estimated*  $7\frac{1}{2}$  H.P. per car will be found a long way below the mark when a line on a practical scale has to be planned, and we would advise the consulting engineer to double this figure in future, otherwise he will jeopardise the whole business. It is admitted that the power required to energise and propel the electro-magnet on the Lineff car involves an extra expenditure of  $\frac{1}{2}$  to  $\frac{3}{4}$  H.P., therefore it may be assumed, all other conditions being similar, that this system is that much less economical than many other existing electric tramways.

The Lineff method of working with closed conduits is in itself ingenious and sufficiently meritorious; but

notwithstanding Mr. Lineff's long letter to us, and Mr. Kapp's report (mainly appendix), we do not anticipate that any sane person will consider that it solves the problem of electric traction. Professional opinions on toy lines are now, we are thankful to say, almost things of the past, and we look in these days for results obtained from actual work on a large scale; we are glad, therefore, to learn that the Lineff method of working is now considered ripe for practical application.

On the insulation resistance of underground conductors and the properties of insulating materials, Mr. Kapp probably would not pose as an authority; yet, he says, that "if the mechanical strain had developed cracks in the bitumen, there would have been sufficient time for water to percolate in the interval of 26 hours which elapsed between the two resistance tests." Now this is an opinion to which our readers may attach whatever value they please, while we proceed to give an example of actual practice. Some years ago, a genial American invaded this country with an insulating material and a method of laying underground wires, which he thought would revolutionise those in use. The insulator was not bitumen, but it served the same purpose and was employed in a similar manner. Our friend secured a contract for laying about half a mile of his underground system, some 60 wires being embedded in a trough containing his material.

The section was laid in summer, and for a few weeks all went right merrily. Not a fault could be found on any of the wires during a series of daily tests, and the inventor was in high glee and predicted that the same happy state of affairs would obtain at the end of as many years. Unfortunately heavy rain soon ensued and lasted, off and on, for a considerable period, and in the course of several more weeks its effects were felt. First one wire fell off in insulation, then another, and before 6 months had elapsed every wire contained in that section had gone bad. The result was entirely due to water lodging around the insulating material and in due course finding its way to the wires, and this, it must be borne in mind, was in a solid block of material, not in a tube or channel. We might instance numerous other examples, but enough has been said to show that in matters of this kind one must await events and not jump to conclusions on the strength of a day's experience.

### ST. PANCRAS VESTRY.

At a meeting of the vestry held on Wednesday, the report of the Electricity Committee was presented for discussion, with the following recommendations attached :—

1. That the seven tenders herein mentioned be accepted.
2. That during the adjournment of the vestry your committee be empowered to clear the site.
3. That the committee be empowered to accept the guarantees for each contract, and to prepare the necessary bonds.
4. That the Finance Committee be instructed to draw a cheque to the order of Prof. Henry Robinson in accordance with the terms agreed upon between the vestry and Prof. Robinson, dated November, 1889, amounting to £994 12s.
5. That a cheque be drawn in favour of Dr. Hopkinson, President of the Institute of the Electrical Engineers, for £105, for services rendered as consulting engineer.
6. That a cheque be drawn in favour of Mr. W. H. Preece, electrician to the Post Office, for £52 10s., for his advice and report upon the plans, specifications and tenders received.

Mr. SWERT, in moving their adoption, observed that it was not proposed to use high tension currents. With regard to a report that the light had been tried in the clearing house of one of the railway companies, and had turned out a failure, he said the committee had waited on the chief of the department, who informed them that the experiment with both the arc and incandescent lamps had been in every way satisfactory, and that a committee was sitting to see whether the light should be made permanent. It was said that the vestry ought to arrange for the lighting of the parish with some public company; but in that case, they must be prepared to waive their rights for a period of 42 years. As sensible men, they would accept their committee's report. Motive power, which companies in London were not making provision for, was provided for in their installation. The committee had had very elaborate specifications and estimates made. Forty-five tenders had been received, and not the lowest merely had been accepted. They had as far as possible, placed them-

selves in actual communication with the manufacturers. The original amount estimated, £60,000, had not been exceeded, notwithstanding that the price of material—copper for instance—and of labour had risen considerably. The committee had been in communication with the Westinghouse Company, which held the patent for the 3-wire system, and although it was proposed to pay £800 or £900 for it, it would enable the vestry to save considerably. When it was suggested that Dr. Hopkinson was himself interested in the 3-wire system the committee took the plans and specifications to Mr. Preece for independent advice, and, in Mr. Preece's opinion, which was appended to the report, Prof. Robinson's installation was to be recommended. Replying to a member, Mr. Sweet further said that the buildings would be erected under Prof. Robinson's superintendence, and that the price for the mains was inclusive of everything necessary for a complete installation.

Dr. FORSYTH argued that if members would read between the lines they would see that Messrs. Hopkinson and Preece merely said that the continuous system was proper for transmitting the supply within the radius of half a mile, and that for over that distance the alternating system was the proper one. The speaker also said that the storage batteries would be a constant source of trouble.

Mr. SWEET, in reply to Mr. Clements, said the report was agreed to on the 25th July. The reason that the printers were busy was the only one he knew of why it was not placed in the hands of members earlier.

Mr. CLEMENTS asked when it was put into the hands of the chief clerk.

The CHIEF CLERK said it had never been in his hands.

Mr. LAMBLE moved that the matter be adjourned until the next meeting of the vestry. He explained that he did so not out of opposition to the scheme which the vestry had pledged itself to, but because very few members had had time to consider the report.

The motion was put to the meeting, and 23 voted for the adjournment and 28 against. Four members hereupon demanded a division, the result of which was that 29 voted for the adjournment and 26 against. A dispute arose as to whether any specific date had been mentioned by the mover, and

Mr. WILSON moved that the vestry meet on the following Wednesday, to consider the report of the Electricity Committee.

Mr. SWEET said that to adjourn the discussion to the date of their next meeting, viz., the first Wednesday in September, would add considerably to the expenses for interest, &c.

Mr. WETENHALL, as a member of the committee, thereupon tendered his resignation.

Mr. WESTACOTT said he had voted for the adjournment because he considered members should have an opportunity to consider a scheme which involved an expenditure of between fifty and sixty thousand pounds; but he suggested that members should be asked to sign a requisition for a special meeting, to be held next week, to rescind the vote for adjournment, by which time every member would have been enabled to consider the report.

This was agreed to, and in the meantime the vote to adjourn the consideration of the question to the second week in September would stand.

A letter was read from Mr. Lazarus, resigning his seat on the Electricity Committee, and shortly afterwards the proceedings ended.

## NOTES.

**St. Pancras Electric Lighting.**—We have received a copy of the Electricity Committee's report adopted on the 25th ult. Doubts seem to have been expressed respecting the practicability of Prof. Robinson's scheme, and Mr. J. E. H. Gordon appears to have gratuitously submitted a competitive plan. The committee, however, places every faith in the ability of their engineer, and in this view they are upheld by the reports of Dr. Hopkinson and Mr. W. H. Preece. This we are pleased to see, for the committee states that the consideration of Mr. Gordon's estimate was more or less forced upon its members. The following contracts, amounting in all to nearly £52,000, have been recommended:—Kirk and Randall, buildings; Babcock and Wilcox Co., boilers, &c.; Willans and Robinson, engines, dynamos, &c.; the Electric Construction Corporation, switchboards and batteries; Mowlem & Co., trenches for five miles of mains; Clark, Muirhead & Co., conductors for five miles of private and 5½ miles public lighting. We congratulate the committee, and also Prof. Robinson, upon the result of their joint labours, and the latter is doubtless more than satisfied that his elaborate scheme should meet with the approval, in almost every detail, of such experts in electric lighting as Messrs. Hopkinson and Preece.

**Lighting in Breslau.**—The town committee has decided to raise a loan of £50,000 for the purpose of erecting a central station. It is probable that the tender of Messrs. Siemens and Halske will be accepted. This project comprises the immediate erection of a station of 8,000 lamps capacity, with a view to an extension to a total of 30,000 lights. Continuous currents will be used in conjunction with accumulators.

**The Berlin-Warsaw Telephone.**—A telegram from St. Petersburg states that a Franco-Belgian group of financiers has asked for a concession authorising the laying down of a telephone line between Warsaw and Berlin. The first two minutes' conversation are to be charged 2 roubles, and the following minutes 25 per cent. less. If the Russian Government approves these prices, the telephone would, on the expiration of the concession, revert to the State.

**Paddington Lighting.**—We understand that in the Paddington district there are to be between 5,000 and 7,000 incandescent lamps in operation by October 1st, supplied from the Manchester Square station. Firms contracting for wiring houses may take this as a hint.

**Adoption of the Electric Light at Barnsley.**—At a meeting of the Town Council, on Tuesday, it was resolved to accept the tender of the Westinghouse Electric Company to light a portion of the borough at a cost of £17,800.

**New Central Station in Berlin.**—The Kurfürstendamm Gesellschaft, in Berlin, will shortly commence operations at their new central station, which will supply current to light up the district of Grunewald. The glow lamps, for street lighting, will be arranged two in series. The total cost of the station, including plant and buildings, is estimated at £15,000.

**Milan Cathedral.**—A company has been formed in Milan for the purpose of electrically lighting the dome of the Milan Cathedral by a large lamp placed on the topmost portion. We wonder what the dividend will be if the company does not supply light elsewhere.

**The Lineff System of Electric Traction.**—We are informed that the Lineff Electric Lighting and Traction Syndicate, the sole proprietors of the English and foreign patents, have received offers to instal their system on several London and country tramways, and also in Paris, Brussels and Italy. A company will shortly be formed, with a capital of several hundred thousand pounds, to execute the above orders. It may be mentioned as significant of the feeling of tramway companies regarding accumulator traction, that one of the directors of the North Metropolitan Tramway Company recently visited the Chiswick dépôt, and expressed himself highly satisfied with the working of the Lineff system.

**Dynamos.**—The dynamo described in our last issue, and referred to in a previous article, is the type now being manufactured by Messrs. Andrews and Preece, Limited, electrical engineers, Borough Mills, Bradford.

**Lighting of New Town Hall, Portsmouth.**—The Portsmouth New Town Hall, which has cost upwards of £140,000, has a very complete installation of the electric light; tried a few evenings since it proved highly successful.

**Large Turbines.**—Messrs. Thomson, Son & Co., of Dundee, have just received an order for twin turbines, each developing 500 H.P., or combined 1,000 H.P. effective. One wheel of similar size has been at work for some years, and these two are supplemental. The type of wheel is parallel flow, largely on the lines of the Jonval turbine, and the fall is 20 feet. The drive is for a large textile factory abroad.

**Lightning Strokes.**—In the Victorian *Electrical and Telegraphic Journal* we read the following:—The following short, graphic description of a lightning stroke has been sent us by Mr. James M'Carter, of Congupna Road:—"Last Monday night (3rd March), during thunder and lightning, without rain, I 'cut out,' and shortly afterwards was shocked by seeing the office apparently ablaze, and hearing a terrific report, similar to that of a gun, but much louder. I fully expected to find the whole front of the office smashed in, and could hardly credit, on examination, that the only damage done was several of the screw points of arrester fused. The point of one screw was flattened on to the centre plate, resembling a small coin. I scraped this off, and found there was an indent on the earth plate."

**The Hub of the Universe again to the Fore.**—The *Boston Post*, of June 14th, contains a long account of the improved system of the Union Electric Car Company. We are gravely assured that the devices of the Union Electric Car Company enable the storage battery to be utilised with marked success, as experience abundantly proves. This electrical device, covered by broad patent claims, enables the battery to receive back a portion of its electrical energy while the car is in motion by converting the motor into a generator. Whenever the car is slowed, stopped, or is running on a downward grade, the motor generates a current that is conveyed back into the storage batteries and partially replenishes the loss of electricity entailed by propelling the car up grades or on a level road. Tests have shown that on the Beverly road the maximum return is more than is taken out at any one time. This return current has never before been produced by a series-wound motor, and it is accomplished by charging the field magnets from a supplementary battery. The comparatively small amount of electricity required to run the cars of the Union Electric Car Company, combined with this process of automatic recharging while in transit, make the use of storage batteries perfectly feasible, while the weight of the car with the batteries in place is 1,000 to 2,000 lbs. less than the ordinary electric car operated by the overhead system. The only thing to be done in England now that the Union Company recovers more than is taken out of the battery at any given time, is to seek permission to use the system. Holroyd Smith, Reckenzaun, Elieson, Lineff, &c., are not within miles of this result.

**Poole and White, Limited.**—On Saturday last week the *employés* of this company took their first annual excursion. The party, which numbered over 30, met at the Elephant and Castle Hotel, Pangbourne, Mr. J. Tryon, the chairman of the company, presiding. The chairman, in proposing the toast of "The Firm," referred to the success which had attended their efforts during the first six months of their existence, and said it was due in great measure to the excellent *esprit de corps* of the *employés*. It was the desire of the directors to establish a reputation for the excellence of their work, and to extend and increase their business and profits by legitimate trading, and not by means of mere financing, and he was pleased to see the way in which every one in the business did their utmost to attain that end. In coupling the toast with the name of Mr. White, he paid a graceful compliment to the ability and zeal with which Mr. White had devoted himself to the interests of the company. Mr. Heaven, who occupied the vice-chair, proposed the toast of "The Board of Directors," to which Mr. Poole suitably replied.

**National Art Competition.**—The exhibition of the works submitted for the National Art Competition, 1890, by the schools of Art throughout the kingdom, was opened to the public on Monday last, and will remain open until the end of August. The works will be on view in the Enamels Gallery of the South Kensington Museum. The free days are Mondays, Tuesdays, and Saturdays, when the museum is open from 10 a.m. to 10 p.m.

**Royal Jubilee Exhibition, Manchester, 1887.**—At the final meetings of the Executive Committee and Guarantors' Council, held prior to their dissolution in December last, the following gentlemen were appointed trustees to hold the surplus funds until all outstanding claims were adjusted, and to hand the net balance over to the Whitworth Institute—viz., Sir Joseph C. Lee, Messrs. C. J. Galloway, Oliver Heywood, and William Agnew. A meeting of the trustees was held last week at the secretary's offices, 46, Brown Street, Manchester, when a final statement of accounts was submitted, showing the net cash surplus to be £41,942 18s. 11d., or, together with the value of certain assets not realised, and which have now been handed over to the institute, £43,492 18s. 11d. A cheque for this amount was drawn and handed to Mr. Oliver Heywood for presentation at the meeting of the institute. The affairs of the exhibition were then declared to be finally closed.

**Lightning in an Engine Room.**—The engine house containing the dynamos which furnish the Viceregal Lodge, Simla, with the electric light, was recently struck by lightning during a storm. At the time there were in the room two native workmen, with Mr. Jordan, the European superintendent. One of the men was struck down, but was brought round immediately afterwards by a plentiful application of cold water; the other man did not fall, but received a severe shock. The lights in the engine house all went out, and the place was in darkness for a short time. Some pieces of mica used in the lightning guard were pierced, and the fastenings torn away.

**The London Press and the Proposed Telegraph Subsidies.**—The *Leeds Mercury*, in a recent issue, comments strongly on the fact that the London daily Press has refused to publish a very important communication deprecating the proposed subsidy to the Eastern Telegraph Companies. We think, with our contemporary, that the incident reflects little credit upon British journalism.

**Improved Fluids for Primary Batteries.**—Mr. Theophilus Coad has invented yet another fluid made of the following ingredients:—Nitric acid, mercury, carbonate of potash, carbonate of soda, bichromate of potash, sulphuric acid, common soda and water. A correspondent writes:—"Where is the patent in this? It is as old as the hills."

**Electric Light Undertakings.**—In the new edition of the "Gas and Water Companies' Directory," published by Messrs. Hazell, Watson and Viney, an electric lighting section has been added, consisting of useful information relating to municipal authorities, companies, and private firms supplying electrical energy for lighting purposes. The following particulars are given of no less than 55 undertakings—name and town, address, date of formation, capital employed, system, capacity of works, price per unit, name of secretary, name of electrician in charge, and area of district supplied. The table appears to have been compiled with care, and the details given must be of interest to almost every one engaged in electrical business.

**Removal.**—The business of telephonic engineers hitherto carried on at 26, Red Lion Square, under the title of The Electric Telephone Company, is removed to Hermitage Works, Richmond, Surrey, where it will henceforth be carried on by Mr. Ernest J. Gillett.

**A Use for the Phonograph.**—A use for Colonel Gouraud's pretty toy has been found at last, and in Arthur Law's new farcical play, "The Judge," the cries of a real infant recorded by the Edison phonograph, on Monday, the 21st ult., are reproduced. The Stage has utilised from time to time most of the contrivances invented in the field of electric lighting, and its adoption of the phonograph adds still another instance of the manner in which scientific progress may be turned to profitable account in the World of Art.

**Consulting Electricians.**—It is very evident that some standard is necessary to which the consulting electrician can adhere, for the unwritten laws of professional etiquette seem quite inadequate. It appears that there are several individuals in existence professing to give advice in electrical matters who are not averse to acting in a manner which should certainly bring them under the serious displeasure of the Institutes to which they belong. What can be thought of any man who, when called in to advise a client who had already arranged to have his requirements carried out by a firm of electrical engineers, coolly says that he (the client) could effect his purpose more cheaply by allowing his professional adviser to hire his own men, and buy the necessary plant for completing the work; and, as if this were not bad enough, he also accepts commissions all round from the firms who supply the goods. We are assured, on unmistakeable authority, that this kind of procedure is being practised, so, how can the *bonâ fide* technical expert, who is ready to give his impartial opinions for a reasonable fee, expect to stand a chance against men who undercut him in the way of payment for professional services, and make up the rest by commissions? One might think that the person requiring technical aid would be cute enough to see through malpractices of this nature, but it appears that such is not the case.

**Electric Railway Conduits.**—We have received a letter from Henry James Peddie giving a description and illustration of his "conduit rail" for electric tramways. The communication is marked "private," yet he concludes by requesting us to notice his invention in the REVIEW. We can only say that the design is a very neat arrangement, without possessing much novelty, and that under more favourable circumstances we should probably have reproduced his drawings. As it is, we refer those interested to Specification 6359, 1890.

**Gas and Electric Lighting on the Continent.**—The European Gas Company, which has always taken a place in the front rank of continental gas companies, during the past year only had an increase in their sales of gas of  $1\frac{1}{2}$  per cent. Enlarging upon this at the meeting of the shareholders last month, the Chairman (Mr. H. McL. Backler), pointed out that this was the aggregate increase at all the stations, but in some cities the increase was more. At Havre, for instance, the increase was at the rate of 4 per cent., but it was a remarkable thing, he added, that at that station there was much more electric light used than at any other. This was not, however, the only instance, but he had observed the same thing in other continental towns. He saw that at Milan, the consumption of gas exceeded that of former times, although in no city in Italy with which he was acquainted was the electric light used to so considerable an extent. He remarked the same thing in connection with Vienna, Berlin and other cities.

**Varley's 1876 Machine.**—This dynamo, which was the rock on which the Anglo-American Brush Corporation split in the recent compound-winding case, is now to be seen in the Edinburgh Exhibition, and will no doubt be an object of the greatest interest to electricians visiting the place.

**More Demonstration.**—On Thursday last week another demonstration was given of the Lineff method of electric traction over the 75 yards of experimental track at the dépôt of the West Metropolitan Tramway Company, Chiswick.

**New Patents.**—Mr. Swinburne has applied for a patent (see p. 142) apparently for five distinct objects. We have hitherto been under the impression that to make inventions valid it was necessary to confine a specification to one object only; perhaps, however, the word "jellygraph" is sufficiently comprehensive to include all the rest.

**Dr. Duncan's Motor.**—Says the *Electrical World*:—"We are now enabled to give some details of the performance of the experimental machine (Dr. Duncan's motor), which give it unquestioned place as one of the most remarkable developments of dynamo-electric machinery. It weighs 1,100 pounds, and in spite of the fact that its armature is solid cast iron, it develops 10 horse-power at the marvellously low speed of 90 revolutions per minute, and accomplishes this feat with an electrical efficiency of 92 per cent. The commercial efficiency was not measured, but as only 25 lbs. of iron are subject to hysteresis, and at a comparatively low rate of reversal, the losses from this cause should be small." How is it known that the motor actually develops 10 H.P., and why has the commercial efficiency not been calculated if brake tests have been applied?

**The Ferranti Mains.**—We hear that part of the main route of the London Electric Supply Corporation is up again in the West End, through the failure of the joints in the new Ferranti cables.

**The Telegraph Clerks.**—We regret to learn that the application of the new scheme is attended with much delay and uncertainty. The vague and ambiguous notices posted in the Central Telegraph Department, to which we referred in a recent issue, have been withdrawn. Interviews with the officials do not seem to be productive of anything definite or satisfactory, and, as several points of vital interest to the staff are still unsettled, a policy of procrastination and mystery is not calculated to have a beneficial or conciliating effect on those interested.

**Tudor Accumulators.**—The well-known manufactory of Messrs. Müller and Einbeck, at Hagen, Westphalia, has been converted into a limited company, with a capital of £225,000. The entire capital has been taken up by the Allgemeine Elektrizitäts Gesellschaft of Berlin, Messrs. Siemens and Halske, and the vendors (Messrs. Müller and Einbeck), in equal parts. The chief office will be situated in Berlin. The Hagen firm, which manufactures the Tudor accumulator, appears to have been very successful commercially, and a German contemporary states that the reason why the Berlin houses have joined it is for the purpose of expanding an existing and prosperous business rather than have to enter into competition with it.

**The British Association.**—We have received a circular containing the names of members of the various local committees, and the arrangements for excursions, to which special attention will be paid at the forthcoming visit of the association to Leeds.

**Dissolution of Partnership.**—The partnership between Messrs. W. D. Ramsay and Cecil Walker, electrical engineers, at No. 1, Prince's Mansions, Victoria Street, Westminster (Ramsay and Walker) has been dissolved by mutual consent.

---

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

---

**Western Counties and South Wales Telephone Company, Limited.**—At an extraordinary general meeting of this company, held at the Grand Hotel, Bristol, on the 30th May, the following special resolution was passed:—"That the articles of association be altered as follows: (a.) By striking out the word 'United' wherever it occurs in Articles 38, 39, 74, 83 and 93, and in sub-clauses of Article 71, and substituting the word 'National' therefor, and by striking out the figures £30,000 in sub-clause (A) of Article 71 and substituting £50,000." The resolution was confirmed on the 27th June and filed July 1st.

The annual return, made up to the 13th June, was filed 26th July. The nominal capital is £400,000, divided into 200,000 preference shares of £5 each and 300,000 ordinary of £1 each. The shares taken are 20,000 preference and 281,197 ordinary. Upon 16,600 preference shares the full amount has been called, and the full amount is considered to have been called and paid upon 3,400 preference and 281,197 ordinary. The calls paid amount to £76,233, including £10 paid on 20 shares forfeited. The unpaid calls amount to £6,777.

**New Cadogan and Belgrave Electric Supply Company, Limited.**—The registered office of this company is now situate at 91, Manor Street, Chelsea.

**Taunton Electric Lighting Company, Limited.**—The registered office of this company is now situate at St. James Street, Taunton.

### NEW COMPANIES REGISTERED.

**Plymouth and District Pulsion Telephone Company, Limited.**—Capital £4,600, in £1 shares. Objects: To acquire a license of the patent rights granted to Lemuel Millett (1888, 9th June, No. 8,457) for improvements in a mechanical telephone known as the Pulsion telephone. Signatories: W. W. Ricksend, 200 shares; A. Jackson, 40 shares; T. Emerson, 200 shares; A. Latimer, 10 shares, all of Plymouth; Wm. Square, 14, Portland Square, 200 shares; F. A. Buckle, B.A., Stoke, 200 shares. The signatories are to appoint the first directors. Qualification, 100 shares; the company in general meeting will determine remuneration after 10 per cent. dividend has been paid. Registered 24th ult., by Sir Joseph Causton and Sons, 9, Eastcheap.

**Edison Phonographic Toy and Automaton Company, Limited.**—Capital, £300,000, in £1 shares. Objects: To acquire certain patents for the application of the phonograph to dolls, toys, and automatic figures. Signatories (with 1 share each): E. J. Cook, 28, Pelham Road, N.; J. Guthrie, Florinda Villa, Lancaster Road, Leytonstone; F. B. Liley, 100, Sundmere Road, Clapham; J. H. Coulson, 76, Oakley Road, N.; S. Cooke, 53, Chadwick Road, Peckham; E. J. Newbatt, 57, Cowley Road, Brixton; G. Bridgland, 8, Sparham Road, Brixton. The first directors are Major-General Sir J. W. Campbell, Bart.; H. G. Hemmerde, T. H. Lambert, Col. A. D. Campbell, and Louis Swaley. Qualification, 250 shares; remuneration, £250 per annum each, with £50 additional for the chairman. Registered 26th ult., by Collette and Collette, 2, Victoria Mansions.

**British Gas Lighting Improvement Company, Limited.**—Capital, £160,000, divided into 6,000 preference shares of £5 each, and 130,000 ordinary shares of £1 each. Objects: To carry on the business of mechanical, gas, and electric engineers and manufacturing chemists in all branches. Signatories (with 1 preference share each):—H. S. King, 65, Cornhill; W. J. Wright, Montagu Mansion, W.C.; F. W. Clark, C.E., South Norwood Park; A. C. Trotman, 12, Thayer Street, W.; J. V. Miller, 39, Stockade Road, Clapham; A. Gooch, 69, Benthall Road, N.; G. Chandler, Woodford. The first directors are:—J. Boustead, Malcolm Guthrie, H. Wollaston Blake, W. L. Hammack, and H. S. King, C.I.E. Qualification, £100 in shares. Remuneration, £200 per annum each, with an additional £100 for the chairman. Registered 28th ult., by Paine, Son and Pollock, 14, St. Helen's Place.

**Mulholland, Maugham and Company, Limited.**—Capital £5,000, in £10 shares. Objects: To take over the business of R. M. L. Mulholland and B. Maugham, at Ferryhill, Durham, trading as Mulholland, Maugham and Co., and to manufacture and deal in apparatus and things required in connection with electrical engineering, and in particular to construct and lay down cables. Signatories (with 1 share each): R. M. L. Mulholland, P. Mulholland, B. Maugham, T. Iseton, J. Sanders, all

of West Cornforth; J. Parker, East Howle; J. W. Mulholland, Hatton, Warwick. The signatories are to appoint the first directors. Qualification, £500 in shares or stock; the company in general meeting will determine remuneration. Registered 29th ult. by Bell & Co., 9, Bow Churchyard.

### CITY NOTES, REPORTS, MEETINGS, &c.

#### Telephone Company of Austria.

Mr. Henry Grüwing presided at the seventh ordinary general meeting of shareholders, held at the company's offices, 53, New Broad Street, yesterday.

The report states:—There has been expended on capital account a further sum of £10,155 11s. 10d. The gross receipts from all sources were £16,524 8s. 8d. After providing for all expenses, including £5,425 4s. 2d. for debenture interest and dividend on preference and interim dividend of 2½ per cent. on ordinary shares, and £3,932 0s. 9d. for royalties and taxes to the Austrian Government, there remains a balance of £1,640 12s. 7d. which, with the amount £3,284 4s. 6d. brought forward from last year, leaves to the credit of profit and loss account for the current year the sum of £4,924 17s. 1d.; of this amount it is proposed to place £3,900 to reserve, and to pay a further dividend of 1½ per cent. upon the ordinary shares (making 4 per cent. for the year), leaving £1,047 2s. 7d. to be carried forward to the next year's accounts.

The Government trunk line between Vienna and Prag, which was alluded to in the last report, was successfully completed and opened for the use of the public towards the end of last year. The undertaking has proved a very great success, and, although the outlay to this company for new switchboards, &c., was considerable, we have reaped the benefit of a fair increase in the number of new subscribers joining the exchange system.

The Austrian Government have now in contemplation the connecting up of other towns worked by this company on the same terms as the Vienna-Prag line, i.e., the Government constructs the trunk line and places the company's exchange subscribers in communication with Vienna, the company having the indirect benefit of the increase of subscribers.

In relation to the prolongation of the company's concessions, the Minister of Commerce has fixed the month of October for opening the negotiations, which, your directors have every hope, will be of a satisfactory nature to the shareholders.

The cordial and satisfactory relations of the Imperial-Royal Telegraph and Postal Authorities and of the municipal bodies with the company remain unaltered.

The Chairman said the progress of the company had been satisfactory during the past financial year, and since the commencement of the current year a further satisfactory increase had taken place, as compared with the corresponding period, of 17,430 florins. He congratulated the shareholders that the year under review was the first of the company's existence in which it had been in a position to declare a dividend on the ordinary shares. It was not that no profits had been made in previous years, but that the necessities of the capital account had been so pressing that every penny of the surplus profits had had to be invested in extending the business. They would now, he did not doubt, reap the benefit of that policy. Their parent, the Consolidated Company, had now made arrangements to supply them with capital to any reasonable amount. He did not doubt that the negotiations pending with the Austrian Minister of Commerce, for the extension of the company's concessions, would have a satisfactory issue. He moved the adoption of the report and accounts, and to declare a dividend on the terms of the report.

Mr. Fitzgerald seconded the motion, which was carried unanimously. Mr. R. E. Bateman was re-elected a director, and Messrs. Deloitte, Dever, Griffiths & Co. auditors of the company; and, with a vote of thanks to the board, the proceedings came to a close.

#### Elmore's Patent Copper-Depositing Company, Limited.

A MEETING of this company was held at Cannon Street Hotel on Monday. The Chairman (Mr. Carson), apologised for the absence of the president of the company. The directors were very glad to be able to meet the shareholders with an excellent record of progress, shown in the following report:—

"Your directors have pleasure in submitting to you the annexed statement of the company's accounts for the period from the date of the company's formation on January 18th, 1889, to June 30th, 1890.

"In March last, the board disposed of the exclusive British license for the manufacture of wire to Elmore's Wire Manufacturing Company, Limited. The shares of this company (£2 each), were issued at a premium of £1, half of which, in addition to the sum of £75,000, went to our own company. The issue was made to about 500 applicants. A total sum of £105,000 has been received from the wire company, and, in addition, our own company has a further interest contingent upon the allotment later on of the balance of shares of the first issue. Our own company holds"

also, all the founders' shares, which are entitled to one-half the profits after 20 per cent. has been paid to the shareholders of the wire company. The board regard these founders' shares as a most valuable asset. It may here be stated that the wire company have received an offer from a strong group of Birmingham firms to take their whole output of wire spirals at remunerative prices.

"The board recommend that out of the sums above-mentioned, an immediate distribution be made of 10s. per share, less income tax, which, with the interim dividend of similar amount paid in April last, makes a total distribution equal to 50 per cent. on the paid up capital for the period named.

"The sum of £20,000, being the estimated original value of the patents for the manufacture of wire, has been reserved, and will be invested or employed in the company's business, as may be deemed most expedient. A further amount of £4,584 8s. 3d. is carried forward, after setting aside £35,000 for the second dividend referred to above."

## BALANCE SHEET, 30th June, 1890.

Dr.	£	s.	d.
To nominal capital—			
100,000 shares of £2 each £200,000, of which there has been issued 70,000 shares, fully paid	140,000	0	0
„ sundry creditors	7,992	12	8

„ interest	785	0	5
„ transfer fees, &c.	206	19	0
	£84,920	5	2
By balance brought down	£77,825	1	4

The Chairman briefly referred to the various items specified in the report. He attributed the great profits made to the change of policy of the board. They would have been at work much sooner had they acted upon the original plan of having the works at Sheffield; but they discovered that their process was capable of large development, and they would require a large amount of land in order that new work could be carried on alongside the parent company, and under the same management. With that view, they obtained a most suitable site at Leeds. The progress of the works

was retarded for several weeks last summer by a strike in the building trade. Further delay in commencing work was caused after the issue of the circular to shareholders, dated February 3rd, 1890, by the breakdown of the first engine supplied for the purpose of driving the dynamos used for depositing. The engine was supplied by a firm of the highest reputation, but had nevertheless proved a complete failure, no useful work having ever been done by it, and it was still incomplete in the hands of the makers, who had undertaken to replace it with an entirely new engine. The breakdown of this engine prevented the management for a period of several weeks from gaining the experience on a large scale with the plant and machinery in the first section of the works, which the board considered indispensable before committing the company to further outlay of capital. The only difficulty experienced subsequently to the breakdown of the engine had been in obtaining perfectly balanced cast iron mandrels or cores for depositing tubes upon. The difficulty had now been fully overcome. The board, however, had now the pleasure to report that everything was proceeding satisfactorily at the works. Two new engines have been delivered, and have been working well for several weeks. The various patent appliances have been tested, and have been proved to work with the utmost regularity. The board consider that the promises held out by the inventors, both as to quality of material and cost of manufacture, have been amply fulfilled. Tubes and wire manufactured on a commercial scale by the company have been submitted to users and experts, and have given the utmost satisfaction, the results being in every case equal to those obtained from samples manufactured in the laboratory, and referred to in the prospectus. At the present time the state of the works is as follows:—Complete offices, laboratory and stores have been provided. A workshop large enough for a 20-ton per week depositing plant has been erected and fitted with engines, machinery and tools. Engine power and dynamos have been provided for depositing 15 tons a week—boiler power for 25 tons a week—and engine and boiler houses, factory chimney, and copper melting furnace have been built on a scale sufficient for the whole works, and for eventual extensions up to 50 tons a week. In addition, a siding connecting the works with the Midland main line has been made. A wharf has been constructed on the canal. The entire property has been walled-in and drained, and two cottages erected. Nothing now remains to be done but to complete the new depositing shed, which will turn out 15 tons per week, and to provide the necessary additional engine power, dynamos, and depositing tanks. The whole of the 20-ton per week depositing plant is in process of completion, and the first section, capable of turning out 5 tons a week, has been satisfactorily at work for several weeks. The works are fitted with the electric light throughout, and an ample supply of copper purchased at prices considerably below the present market quotations has been provided. The demand for the company's products is far in excess of this 20-ton plant, and the prices obtainable are most remunerative. Now that the work connected with preparing for the two exhibitions is over, the whole of the available plant is engaged in the execution of orders.

Several shareholders were dissatisfied that there was not a sufficient sum placed to the reserve, and an amendment was proposed, which was, however, defeated.

A shareholder commented strongly on the defective engine supplied, and considered there was little excuse.

All the members of the board were re-elected, as were the auditors.

## Direct United States Cable Company, Limited.

THE twenty-sixth ordinary general meeting of the company was held at Winchester House on the 25th ult., when the report (printed in our last issue) and balance sheet for the six months ending June 30th, 1890, were produced.

The Chairman, Sir John Pender, K.C.M.G., said the revenue for the half-year, after deducting out-payments, amounted to £40,017 1s.; working and other expenses, including income tax, but excluding cost of repairs of cables, amounted to £17,616 5s. 8d., leaving a balance of £22,401 as the net profit of the half-year, making, with £8,318 brought forward from the previous half-year, £30,718 14s. 8d., which had been appropriated thus: interim dividend of 3s. 6d. per share for the half-year ending March 31st, 1890, amounting to £10,624 5s., and a proposed final dividend of 3s. 6d. for the half-year ending June 30th amounting to £10,624 5s.; transfer to reserve fund £8,502; balance forward £968; total £30,719. The revenue for the earlier portion of the half-year showed some falling off as compared with the corresponding period, the tariff being 1s. in each case, but in the latter months an improvement took place which more than recouped the previous falling off, and resulted in a small increase of £390. The reserve fund, after deducting £4,919, cost of repairs, and crediting it with £4,389, interest on investments, and profit on sale of securities, and with £8,502 transferred from the revenue account, amounted to £250,000. The investments were, as heretofore, considered to be worth more than the figure standing in the balance sheet. At their last meeting he expressed the opinion that six months hence it would be necessary to draw special attention to the reserve fund. That fund had been drawn upon to some extent to supplement the company's dividends, and to maintain the 3½ per cent., which otherwise could not have been paid with the 6d. tariff. On the present occasion it would not be necessary to appeal to the shareholders in any way in connection with the reserve fund. It seemed to have turned the corner; they had for the first time during the last two or three years been

adding to instead of taking from it, until it was increased to a very nice round sum. By carrying out the principle laid down, of adding the interest to the reserve fund, and also such a sum as could be conveniently spared from the income, he hoped the company would eventually be placed in a thoroughly independent position, and he believed it occupied such a position that day. He believed their cable stood at a very much lower cost than any other cable in the Atlantic, and that with this large reserve fund no other company could compare with it in value. Standing as it did at, comparatively, a very small price, it was, at any rate, just as good as any other cable in the Atlantic standing at three or four times the price. It was in such good order that the duplex system could be worked upon it. Practically, therefore, the company had the command of two cables, and he was very pleased to say was doing its full share of the Atlantic traffic. As the pool was at present, there was an impression abroad that a single cable was a very dangerous investment. However, when he told them that the cable was one of seven in the Atlantic, they would understand that if the company's cable became incapacitated for twelve months, it would not interfere in the slightest degree with the company's income, as the other cables would be quite sufficient for the traffic; or if the company's cable should be incapacitated for two years, the shareholders would still have an income, and even if it became incapacitated for three years, they would still have a small income. Let it be distinctly understood that if the company stood as a single cable, it was nevertheless guaranteed by six others. That was a very strong position to occupy, and, taking it in connection with the reserve fund, he looked upon the company's cable as the cheapest in the Atlantic. A fault occurred the other day, it was very difficult to repair a fault under £5,000; and it was a consolation to think that these faults were not owing to any real decay of the cable, but were caused by the anchors of fishing boats. The directors had done all they could to induce fishermen when they took up the company's cable, to drop it; they had even undertaken to find them new gear, and in the past few years, although cables had been broken in this manner, the company had received a good deal of consideration on the part of the fishermen. It had always been the directors' policy when a break occurred, not to hesitate in sending out a ship, in whatever weather, to repair it, and the company had been singularly prompt with its repairs. The directors considered it to be the company's duty to the pool to do a fair and full share of the work, and he believed they were doing their fair proportion of it at present. It was encouraging, if not so much so as he could wish, that at the present moment, with a shilling tariff, the company carried as many messages as it did with a sixpenny tariff. Still it was not earning the amount of money such a risky operation entitled it to; but he hoped that by some combination or arrangement material economies might be made which would enhance the company's dividend. They must endeavour to work this out somehow—he was not prepared to say how. Still it was a magnificent property, and while it was necessary that these submarine cables should be efficiently worked, it would be a reflection on all concerned if they could not arrange in some way to give a fair return to their shareholders out of what had become a great political and commercial necessity. The directors would always bear in mind that a company like this should be just as well as generous. The pool was probably stronger than it ever had been. Regarding the Telegraphic Conference, he was pleased to say that while the company's cable had not been very much under consideration, it had nevertheless been fairly considered by the other companies, and its demands had been settled upon a basis which ought to be satisfactory to all. It had, at any rate, lost nothing by the conference. In conclusion, he assured the meeting that if by any possibility their old dividend of 5 per cent. could be recovered, they might depend upon the board doing its utmost to bring about that result. He moved the adoption of the report and accounts, and to declare a final dividend of 3s. 6d. per share, free of income tax, making with the interim dividend already paid, a total of 3½ per cent. for the year ending 30th June, 1890.

The motion was seconded by Mr. Ford, and unanimously agreed to.

Messrs. Charles Meara and E. M. Underdown were re-elected directors, and Messrs. J. G. Griffiths, F.C.A., and John Sawyer, F.C.A., were reappointed auditors.

A vote of thanks to the board, and one of sympathy with the chairman in his recent bereavement, were unanimously carried, and the proceedings terminated.

### Manchester Edison-Swan Company, Limited.

The eighth annual meeting of the shareholders of this company was held on Monday at Manchester, Mr. V. K. Armitage, chairman of the company, presiding.

The Chairman, in moving the adoption of the report, said the directors were not as satisfied as they might be with the result of the year's operations. Instead of making something over 10 per cent., as they did last year, they had only made something over 5 per cent. They had worked just as hard in making the 5 per cent. as they did last year in making 10. The real fact was that at this moment there was a manifest falling off all over the country in the demand for small separate installations. There was no doubt whatever that the electric lighting would increase enormously in the near future, but their strong impression was that the increase would be in lighting from central stations. Parliament had been issuing provisional orders for central stations broadcast all over the country, and there could be no doubt that

many people who wished to have the electric light were now waiting to see what would be the outcome of these provisional orders. Before they went to the expense of securing private plant they were waiting to see whether they could not draw their supply of electric light from a central station, as they did now in the case of gas. At the same time he had not the smallest doubt that in the near future there would be an enormous increase in the electric lighting industry, and with the experience the Edison-Swan Company had had in this district, and with the name they had acquired for doing good work, he had not the smallest doubt that when the increase came the company would receive at least its fair share of the work that had to be done.

The motion for the adoption of the report was seconded by Mr. I. C. Waterhouse, and carried unanimously.

On the motion of the Chairman, seconded by Mr. Waterhouse, it was further resolved that the profit of £1,647 6s. be appropriated to payment of a dividend at the rate of 5 per cent. per annum (£1,000), carrying forward the balance of £647 6s.

Sir Joseph C. Lee and Mr. I. C. Waterhouse were re-elected directors of the company; and Messrs. Jones, Crewdson & Co. were reappointed auditors.

### The Edison and Swan United Electric Light Company, Limited.

THE seventh annual report of this company (printed in our last issue) was presented to the shareholders at the meeting held in the Cannon Street Hotel, on Monday, the 28th ult., Mr. J. Staats Forbes presiding.

The Chairman said it was one of the most embarrassing reports he had ever had to deal with. As it needed no apology, he was scarcely at home with it. He was old enough to remember when the meetings of the Edison and Swan were not quite of this character, because the results were not quite so satisfactory. Good wine needed no bush. The report itself was exceedingly brief; the facts were chiefly to be found in the figures, which he would deal with somewhat generally. The important item, of course, was the profit and loss account, and the important part of it was that the balance to its credit, after making every fair and proper deduction, was the very respectable one of £61,115 3s. 3d., enabling the company to devote it, if the meeting approved, to the full payment of 7 per cent. upon the capital, and a very considerable contribution in respect of those years, which were sadly too long, when, he remembered, there was no dividend to pay. They knew that the dividend upon the ordinary stock to the extent of 7 per cent. per annum was cumulative, i.e., in the years when it was not secured by the profits any balance would be carried forward as a claim on the future. Last year was the first in which they had been able to devote a portion of the profits to wiping out arrears. This year he was happy to say they were able to devote a much larger sum for that purpose. Beginning on the debtor side, the stock on hand brought forward on the 1st of July, 1889, was £25,985 18s. 2d. He reminded honourable proprietors that the character of the business demanded that a very large amount of capital should be locked up in stock. These lamps were of great variety in form and power, and a great many people had very different ideas as to the voltages and the form they needed; and in order to be in a position to supply the demand, the company must have a very large and various stock on hand. On the opposite side of the account there was a very large increase—from £25,985 18s. 2d. to £56,266 8s. 10d. He would say at once that only a very small proportion of it was attributable to the increase in lamps, it having kept pace almost in arithmetical proportion with the increase in sales. A very large portion of the increase was due to purchases of platinum, which, with a certain amount of forecast, the directors had availed themselves of the opportunity of buying at prices which now, he feared, were very considerably exceeded. That platinum was carried into the account at cost price, and was held in reserve. In round numbers, that would account for some £25,000. The demand for platinum was increasing, and the supply did not appear to keep pace with the demand. Putting two and two together, the directors thought the price might go up, and had, therefore, laid in a considerable amount. For wages, purchases, &c., there was an item of £73,719 2s. 1d.; cost of conducting the business, £13,915 19s. 9d.; depreciation of plant, £1,838 17s. 9d.; and, on the other side, sale of lamps, fittings, &c., £118,865 15s. 1d.; interest on investments, £1,442 17s. 1d.; stock in hand already adverted to, £56,266; balance, £61,115 3s. 3d. The proposed appropriation was a very simple one. On one side was the balance of profit, £61,115 3s. 3d., and on the other what was proposed to be done with it. There was the dividend for the year ending 30th December, 1889, at 7 per cent. per annum, £12,371 14s. 7d. of which had been paid as interim dividend, and which amounted to £24,743 9s. 2d., and there was the claim upon the further profit. The accounts were kept from year to year, and the debt against each year wiped out, beginning with the more remote. The directors proposed to pay the balance of the cumulative preference dividend on the A shares, for the year ending 30th June, 1884, at the rate of 4 per cent., and that payment not having exhausted the balance, they proposed a further payment on account of cumulative preferential dividend on the A shares at the rate of 4 per cent. for the year ending 30th June, 1885. With that they had still £8,093 9s. 5d., which they proposed to carry to the reserve fund. Taking next the reserve capital account, there was no substantial alteration observable.

The capital was exactly as in the last account; the only figure affected was that under B shares. Those shares were entitled to one-fourth of the profits, after payment of a cumulative preferential dividend of 7 per cent. per annum upon the A shares. The preferential cumulative dividend of 7 per cent. amounted, on the 30th June, 1890, to £110,609 17s., the balance amount remaining to be wiped out of future profits amounting to £26,257 5s. 5d. There were sundry credit balances, a reserve fund of £4,595 10s. 10d., which, if the shareholders confirmed the resolutions which would be presented to them as to dividends, would be further increased by £8,093 9s. 5d. On the opposite side of the account they had an item of £235,614 9s. 3d., cost of patents, goodwill, preliminary outlay, loss on working, &c., as per last balance sheet. That had been from time to time subject to diminution by writing down realisation of property and so forth to the extent of £2,030 15s. 6d., against which there was a sum of £2,439 5s. 1d., as further expenditure incurred in extension of works or other purposes only chargeable to capital, and the amount now stood at £236,022 18s. 10d. Then there was the item—amount of "B" shares issued as per contra, £117,820. The shares referred to were those given to Mr. Edison and his friends as the value of their interest in the concern. They were deferred to the others, and some day—he hoped not a distant one—they would come in for a fourth of the profits of the undertaking, after paying 7 per cent. Other assets of the concern were:—Manchester Edison Swan Company, Limited, £100,000 "B" shares, at nominal cost, amounting to £12,000; freehold property, £33,396 9s. 7d.; plant and stock, £77,221 2s. 11d., including the large amount of £56,266 8s. 10d. referred to above; office furniture, £256 17s. 2d.; debtors, £15,203 15s. 11d.; investments, £27,500; and cash at banker's and in hand, £31,563 0s. 6d. Not an inconsiderable amount of the company's capital was that item of freehold property. That property of a going concern, embracing as it did, the lamp factory at Ponder's End, which was bought very cheaply indeed, on which some money had been spent, and which was being extended from time to time, in order to meet a possible very great demand for lamps, was set down at the very safe figure of what had been spent upon it. The item, office furniture, was happily disappearing. The debtors included bad and good. The account appeared to be a tolerably satisfactory one, and the shareholders might feel assured that very liberal allowance had been made on all heads on the debit side, and that the balance was absolutely without charge in respect of any cutting down or holding back of responsibilities which the current revenue ought to bear. He moved the adoption of the report and accounts, and to declare the following dividends:—(a) At the rate of 7 per cent. per annum, upon the "A" shares of the company, for the half-year ending June 30th, 1890, making 7 per cent. for the year; (b) 4 per cent., in completion of payment of arrears of cumulative preference dividend, for the year ending June 30th, 1884; and (c) 4 per cent., in respect of arrears of cumulative preference dividend for the year ending June 30th, 1885, to be distributed in accordance with Clause 87 of the articles of association.

The motion was seconded by Mr. Leyland and carried unanimously.

Mr. Shelford Bidwell was re-elected a director, and Messrs. Welton, Jones & Co. were reappointed auditors.

The Chairman, replying to a vote of thanks to the board, said he believed the reason why the company had emerged from what at one time seemed to be a very perilous position, was the strong conviction which the board possessed that the concern was worth fighting for, and the exercise of a great deal of courage, combined with a good deal of forecast and prudence in insisting upon the rights of the company being upheld. Had the board not felt that it had a proprietary which trusted it entirely, and showed its confidence in it upon every occasion of good and evil report, it might in certain moments of anxiety, when the patents were being fought for, have broken down. It was the shareholders' confidence in the board which kept it going, and he was very glad to think that it had been earned, and that it was continued now that the company was in better and smoother water.

### The Globe Telegraph and Trust Company, Limited.

The seventeenth ordinary general meeting of the company was held on Tuesday, the 29th ult., at Winchester House, to receive the report and accounts for the year, &c. Sir John Pender, K.C.M.G., presided. The report states:—

"The net revenue of the company for the year, after deduction of expenses, amounts to £193,499 4s. 10d., which, with the balance of £2,054 10s. 6d. brought forward, make a total of £195,553 15s. 4d. From this amount there has been distributed the sum of £130,806 5s. 8d. in interim dividends, leaving an available balance of £64,747 9s. 8d.

"The directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares, and of 4s. 3d. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income tax, upon the preference and 5 per cent. net upon the ordinary shares (against 4½ per cent. for the preceding year), and carrying forward a balance of £118 18s. 6d.

"Since the last report 80 shares of the German Norwegian Company have been drawn for amortisation and paid off at par less exchange. It is probable that this cable may be acquired by the German Government within a short period. £890 stock of the Submarine Telegraph Company has been paid off, at 107 per £100

stock; there is still a small return to be made by the liquidators. £200 of the Société Carmichael has been paid off. A further 350 American Cable Company's (\$100 fully paid) shares with 5 per cent. guarantee of the Western Union Company of New York have been added to the investments.

"The directors record with much regret the loss of their colleague, the late Sir Daniel Gooch, Bart. They have elected Mr. James Pender in his stead.

"In conformity with the articles of association William Ford, Esq., and Sir Henry Daniel Gooch, Bart., two of the directors, retire, but, being eligible, offer themselves for re-election.

"The auditors, Mr. John George Griffiths, F.C.A. (Messrs. Deloitte, Dever, Griffiths & Co.), and Mr. William Griffith, B.A., barrister-at-law, also retire at the meeting, and offer themselves for re-election."

The Chairman said, were he to repeat the remarks made by him on the last occasion, they would be quite appropriate to describe the present state of affairs. On that occasion he pointed out that there was a considerable amount of prosperity prevailing in the telegraph system generally. They had terminated their battle in the Atlantic, and were receiving as many messages at the shilling rate as they had previously been at the sixpenny rate; and, of course, their exchequer and, eventually, their dividends had been materially contributed to. During the last three years the company had been steadily progressing, just as the submarine companies had progressed, and to-day it occupied, on the whole, a very satisfactory position. The company during the year received £198,466 4s. 2d., and after deducting working expenses, there was a balance of £193,499 4s. 10d. A sum of £130,806 had been distributed, leaving an available balance of £64,700 for the final dividends, which the directors recommended, of 3s. on the preference shares, and 4s. 3d. on the ordinary shares, or a net dividend of 5s. per share on the ordinary shares, as against the £4 12s. 6d. paid last year. A small balance was carried forward, but the company, being a trust company, was not bound to pay any large amount to the reserve. Taking the combined dividends of preference and ordinary shares during the seventeen years of the company's existence, they found an average dividend of £4 6s. had been paid. The directors hoped to maintain the level of the present year's dividend, viz., 5 per cent. With regard to submarine companies, it might be said the result of the Paris Conference had not been unfavourable. The policy of these companies was the very broad one, not only doing their work well, but so as to satisfy their customers and the general telegraphing public. The other day the British East African Company held a meeting in London, in which some idea of its work was given; but, unfortunately, it was not stated that the Eastern (Telegraph) Company had at its own cost laid down a cable to connect the British East African Company's important port of Umbassa with the still more important one of Zanzibar. That it had done entirely at its own cost, and entirely in the interest of the British East African Company. The policy of the submarine cables was to follow the flag and to follow the trade wherever they found trade and civilisation alongside, so as to help them on. The changes as regards submarine companies had been very few in the last year, and the Paris conference would not materially affect them. One of these companies, the Eastern Extension, had made an arrangement with the Australian Governments to make the very bold experiment of reducing the tariff from 9s. 4d. to 4s. That had been done by the colonial governments guaranteeing the cable companies 50 per cent. of any loss. But the directors of these companies were so confident that the reduction of the rate would double the traffic, that they had not hesitated to take their part in the risk. The policy of the companies was a broad one, and the broader the more prosperous it was; and as the prosperity of the Globe Company was dependent on the success and prosperity of the cable companies, the shareholders might feel confident that what the other companies did would materially benefit their company. Changes in the company's investments had been very few. It had acquired 350 of the American Cable Company's shares. That company was guaranteed by the Western Union Company of New York, and the shares had been bought at a price which admitted of a fair return. The German Government had taken over all the interests the company had in the German Union Company's shares, and these had disappeared from the statement of the company's assets. There only remained the German Norwegian line, which no doubt would ultimately be acquired by the German Government. Having alluded to the loss sustained by the company in Sir Daniel Gooch, Bart., he moved the adoption of the report and accounts, and to declare a dividend of 3s. per share on the preference shares (less income tax) and 4s. 3d. per share on the ordinary shares (free of income tax, already deducted), making, with the former distributions, a total dividend for the year of 6 per cent. upon the preference shares (less income tax) and 5 per cent. net upon the ordinary shares.

The Marquis of Tweeddale seconded the motion, which was carried unanimously, the retiring directors and auditors were re-appointed, and, with votes of thanks and condolence, the meeting dissolved.

### Anglo-American Telegraph Company.

The report of the directors, to be laid before the ordinary general half-yearly meeting of the proprietors, to be held in the Great Hall, Winchester House, 50, Old Broad Street, in the City of London, to-day, at 2 p.m., states:—The total receipts from

the 1st January to 30th June, 1890, including the estimated balance of £2,247 12s. 8d. brought forward from the last account, are estimated at £152,989 7s. 11d. This amount, however, is subject to revision, as the law-suit between this company and the Paris and New York Telegraph Company is still pending. The traffic receipts show an increase of £2,025, as compared with the corresponding period of last year. The total expenses of the half-year, including the new offices in New York, repair of cables, &c., as shown by the revenue account, amount to £53,945 9s. 7d. One quarterly interim dividend of 12s. 6d. per cent. on the ordinary stock, and of 25s. per cent. on the preferred stock, was paid on the 1st May, 1890, absorbing £43,750, and a second quarterly dividend of 15s. per cent. on the ordinary stock, and £1 10s. per cent. on the preferred stock, will be paid on the 1st August, 1890, amounting to £52,500, leaving a balance of £2,793 18s. 4d. to be carried forward to the next account. The company's repairing ss. *Minia* has been engaged during the past half-year in the repair of the Northern Placentia cable, near Placentia, and of the St. Pierre-Duxbury cable, 270 miles from St. Pierre. The vessel was chartered to the Direct United States Cable Company on two occasions for executing repairs, the remuneration for which will be found in the revenue account. The company's cables and land lines are in good working order. Three new offices have been opened in New York, viz.: No. 8, Broad Street; 16, Beaver Street; and 446, Broome Street. The results are encouraging. No progress has been made since the last report in the litigation between the Anglo-American Telegraph Company and the Paris and New York Telegraph Company, the appeal to the Conseil d'Etat not having come on for hearing. The agreement between the Société du Cable Transatlantique Français (amalgamated with the Anglo-American Telegraph Company in 1873) and the Submarine Telegraph Company, for the laying, maintenance and working of the cable used by this company from Brest to Salcombe expired on the 31st March, 1889. The French and English Governments bought the Submarine Telegraph Company's property, with the exception of the cable above referred to, and, after long negotiation, this company has purchased the Brest-Salcombe cable from the liquidators of the Submarine Telegraph Company for the sum of £2,000, and by arrangement with the associated cable companies this company now maintains and works the cable for an agreed annual payment, which forms a charge upon the joint purse receipts.

### The Chili Telephone Company, Limited.

The first annual report of the directors, for the year ended March 31st, to be presented at the meeting of shareholders at Winchester House, on the 8th August, states:—

The whole of the 40,000 shares offered in August last were subscribed for and allotted, and the full sum of £5 has been since received on each share. The purchase money of the properties in Santiago, Valparaiso, Concepcion, Iquique, Chillan, Talcahuano, Talca, Pisagua, Serena, Coquimbo, Tomé, Penco, Coronel, and Lota, has not yet been paid in full to the vendors. The transfer of these properties was, in due course, made to this company by the vendor company in America; but some shareholders of that company, resident in Chili, obtained an injunction to restrain the legal registration of the transfer, with the view apparently to secure to themselves a larger proportion of the vendor company's assets than would fall to them upon a *pro rata* division with the shareholders in America. The action in the Chilean court is between the vendor company and a small minority of its shareholders. This company is not a party to it, but the board has used, and is using, its best endeavours to remove the impediment to the legalisation of the transfer. Negotiations are reported to be pending to settle the differences by compromise or arbitration; either mode would raise the injunction, and allow registration to be completed. After much correspondence and considerable loss of time, the vendor company appointed this company's general manager in Chili to be the general manager of the vendor company there, and, consequently, since that appointment the business has been conducted without serious inconvenience. The business has been carried on for this company since 1st May, 1889, and the net profit to 31st March, 1890 (after providing for the extraordinary depreciation in currency) amounts to £5,520 8s. 1d. The directors recommend a dividend of 2s. 6d. per share, being a fraction more than at the rate of 5 per cent. per annum from the time the capital has been received to the 31st March last. This will leave £520 8s. 1d. to be carried forward to the account of the next year. The business is progressing satisfactorily.

	1st May, 1889.	31st March, 1890.	Increase.
The number of Subscribers was ...	2,070	2,868	798
The gross revenue was at the rate per annum of ...	\$225,357	\$300,346	\$74,989
The mileage was ...	2,523	3,320½	797½

The above increases were during 11 months only. The general manager in Chili has every confidence that, in the current year, very much more favourable results will be shown, and his estimate of improvement is confirmed by a continuous and rapidly increasing demand for telephones. Negotiations have lately been opened for the sale to this company of the property, plant, and business of the National Telephone Company of Chili (National Co. Telefonos Chile), in Santiago and Valparaiso, and the directors have been advised by cablegram of the purchase of the whole for £36,000.

That company was the only competitor with this company, and the directors having now, practically, the control of the telephone business in Chili, anticipate that the company's revenue will be considerably increased; while the requirements of the public will be fully met by necessary extensions and moderate and more uniform charges. In accordance with the articles of association, the Hon. F. Ernest Allsopp and Mr. Thomas Greenwood retire from the board of directors, but, being eligible, offer themselves for re-election. The auditor, Mr. Thomas A. Welton, also retires, and offers himself for re-election.

### Spiel's Petroleum Engine Company.

An extraordinary general meeting of the company was held on the 29th ult. at the offices, Leadenhall Buildings, 11, Leadenhall Street, for the purpose of explaining the present position of the company.

Major J. Heritage (the chairman) stated that an end had been put to all litigation, and questions between the company and Messrs. Shirlaw & Co., who had surrendered the exclusive licence held by them, and the company were fortunate in having come to arrangements with Messrs. Clarke, Chapman & Co., engineers, of Gateshead, whose licence would, however, not be an exclusive license. The company was free to grant licences to other people, with one exception. Messrs. Clarke, Chapman & Co. attached considerable importance to having the exclusive right of manufacturing the installation machines, and that had been given them. The prospects of the company were now much more promising. He moved that the directors be paid £250 per annum, and whenever a dividend of 10 per cent. or upwards shall be paid, an additional 10 per cent. upon the net profits.

Mr. R. A. Tiessen seconded the resolution.

Mr. Neal moved as an amendment that the resolution should stand adjourned for 12 months, in order that a statement of accounts, showing the exact position of the company, might be presented.

Mr. G. Williams seconded the amendment.

Several shareholders expressed a doubt if the company had money in hand sufficient to pay the directors if the resolution was agreed to; but eventually the amendment was negatived.

### The Maxim-Weston Electric Company, Limited.—

An extraordinary general meeting of the Maxim-Weston Electric Company, Limited, will be held at Winchester House, Old Broad Street, in the City of London, on Thursday next, for the purpose of considering and, if deemed expedient, passing the subjoined extraordinary resolution which is intended to take effect under Sub-section 3 of Section 129, of the Companies Act, 1862, "That it has been proved to the satisfaction of this meeting that the company cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same, and accordingly that the company be wound up voluntarily." Should the resolution be duly passed, a further resolution will be proposed at the same meeting for the appointment of a liquidator or liquidators for the purposes of such winding up.

**The Schanschieff Electric Light and Power Company, Limited.**—Creditors of this company are to send their names and addresses and particulars of their debts or claims, to Messrs. S. de Lissa and H. A. Campbell, care of Richard Rabbidge, 32, Poultry, London, on or before 4th August next, or to be excluded from any distribution made before such claims are sent in.

**The Patent Electric Fire Lighter Company, Limited.**—It has been decided to wind up the company voluntarily under Companies Acts, 1862 to 1867. Mr. W. J. Finch, of 21, Osborne Road, Broadstairs, is the liquidator. The assets of the company will be sold to a new company called the New Electric Fire Lighter Company, Limited, partly for cash and partly for debentures.

**Woodhouse and Rawson Electric Supply Company of Great Britain, Limited.**—The petition for the winding up of this company, presented by Major Goodrich Holmsdale Allfrey, of Wakefield Park, Mortimer, Berks., will be heard before Justice Stirling, on Saturday, the 2nd August.

**Elmore's Patent Depositing Company, Limited.**—Application has been made to the committee of the Stock Exchange to appoint a settling day and grant a quotation to this company.

**The West Coast of America Telegraph Company.**—The directors have declared an interim dividend of 3s. per share for 1890.

**Chili Telephone Company, Limited.**—The directors in their report to March 31st last, recommend a dividend of 2s. 6d. per share, leaving £520 to be carried over.

### TRAFFIC RECEIPTS.

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending July 26th, amounted to £4,750.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending July 26th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,679.

## COUNTY COUNCIL AND ELECTRIC LIGHTING.

ON Tuesday last, at the final meeting of the London County Council before the vacation (Sir John Lubbock in the chair), Mr. F. B. Westacott, as Chairman of the Highways Committee, reported that they considered that it would be desirable for the Council to authorise them to deal during the coming vacation with any matters within the scope of their reference which might require immediate action on the part of the Council. The Council was aware that it possessed extensive powers under the Electric Lighting Orders and Acts, which might have to be exercised before it reassembled, and other matters might arise requiring immediate attention. Should this authority be given, the committee proposed to report to the Council, at the first meeting after the recess, what, if anything, had been done under it. They recommended, and the Council resolved:—"That the Highways Committee be authorised to deal, during the ensuing vacation, with any matter within the scope of their reference, which may require immediate action on behalf of the Council."

The same committee reported that they had considered a notice (registered No. 97), dated 16th July, 1890, from the London Electric Supply Corporation, of intention to lay distributing mains in Stanhope Street and Park Lane, as shown upon a plan submitted with the notice. The proposed works were of the same kind as those of this company previously approved by the Council; and the committee recommended: "That the sanction of the Council be given to the works referred to in the notice (registered No. 97), dated July 16th, 1890, of the London Electric Supply Corporation, upon condition that the company do give three days' notice to the Council's engineer before commencing the works; that the mains be laid under the footways, and be kept 9 inches below the underside of the pavement, wherever it is found to be practicable; and that where the mains cross carriage-ways they be kept at the same depth below the concrete."

This was agreed to.

The Parliamentary Committee reported as follows: "We understand that another Electric Lighting Confirmation Bill is to be introduced, and that it will contain orders affecting the City of London. We were authorised on the 3rd June last to present a petition against any order which does not comply with the Council's resolutions of the 28th January and 22nd April, 1890, and we have authorised the preparation and presentation of petitions in the event of any of the orders not complying with the above-mentioned resolutions. We recommend: "That the employment of two counsel be authorised to support the petitions, if necessary." This recommendation was approved.

## LEGAL.

**Gibbs and Others v. Ferranti.**—This appeal came before the Lord Chancellor, Lord Herschell and Lord Morris, in the House of Lords last Thursday. It was an appeal against an order of the Court of Appeal affirming an order of Mr. Justice Kekewich, by which it was ordered that the Gaulard and Gibbs Patent, No. 4,362, A.D. 1882, should be revoked.

Mr. ASTON, Q.C., and Mr. J. C. Graham appeared for the appellants; and Sir H. Davey, Q.C., and Mr. Moulton, Q.C., for the respondent.

The patent was granted in 1882 for an alleged invention of a new system of distributing electricity for the production of light and power by secondary generators, the invention being described as consisting in "the employment of an alternating current produced by an electro-dynamo machine, and determining by its passage through an unlimited number of induction coils of special construction the creation of induced currents, whose quality and value depend solely upon the construction of the said induction coils." In 1886 the respondent presented a petition for the revocation of the patent, and the appellants thereupon applied to amend their specification by disclaimer, and the specification was accordingly amended. The Court of Appeal held that the effect of the amendment was to alter the nature of the invention for which the patent had been originally granted, and therefore revoked the patent.

Their LORDSHIPS affirmed the decision of the Court below, and dismissed the appeal with costs. Judgment affirmed and appeal dismissed with costs.

**The International Cable Company, Limited.**—The petition of Alfred Sohler Bolton, a member of a large firm of wire manufacturers at Cheadle, for the winding up of the International Cable Company, Limited, was again before Mr. Justice Stirling on Saturday. Mr. Graham Hastings, Q.C., having stated the case for the petitioner on the 19th inst.

Mr. BUCKLEY, Q.C. (with whom was Mr. John Chester), replied on behalf of the company. He said that his lordship had already delivered a judgment in this matter by which, of course, he was bound. The petitioner was a member of a firm of wire manufacturers, and had taken 1,000 shares in the expectation that he would be repaid by a contract for wire for the company. In the former decision his lordship came to the conclusion that the main

object of the company was that stated in clause A of the memorandum of association, viz., to establish, maintain and work lines of telegraphic communication between the Azores and points on the coast of Canada and elsewhere. Now, his observation upon that would be this:—Clause A was not to work lines of telegraphic communication under a particular concession, but was to work particular lines of telegraphic communication. His lordship came to the conclusion that the real and primary object was to work the concession from the Portuguese Government, which had been referred to in the prospectus. What his lordship thereby held was that the object of the company was to establish, maintain and work lines of telegraphic communication between this country, Portugal and the Azores; and the question now was—Had that object become impossible, in the sense that this company could not carry it out, and was one shareholder, not supported by others, entitled to say the business had become so impossible that he was entitled to the winding-up order, although the other shareholders did not agree with him, and although no meeting had been called to consider whether this course should be followed or not. Admitting, for the sake of his argument, that the date had passed, the Portuguese Government had neither declared the concession forfeited, nor had they expressly continued it. But, on the 5th inst., a measure to allow, promote, and support by a subsidy the laying and maintenance of a cable from Lisbon to the Azores was passed; and his evidence was that Signor Cavallo, who was largely interested in this company, and who had great influence with the Portuguese Government, expected to obtain the concession under this measure, and would be willing to transfer it to this company. The object of the company, therefore, was, he submitted, not impossible.

Mr. WARRINGTON, for 3,410 shares, which he said represented £34,100, supported the petition.

His Lordship, without calling on Mr. Hastings to reply, said he thought that the order must now go. On the evidence now before him he was perfectly satisfied that the original concession granted by the Portuguese Government, on the faith of the existence of which the shares were subscribed, was completely gone, so completely that a new law had been passed by the Portuguese Legislature authorising a new concession altogether. His view was that this company was formed to work that original concession, and, though the objects of the association were not limited to that particular concession, still that particular concession was mentioned in the prospectus, and by the terms of the prospectus a large portion of the capital was to be appropriated to carrying out that particular concession. That concession was gone. All that now appeared was this; there was a suggestion that the Portuguese authorities were likely to grant the new concession (which by the recent legislation, they had been authorised to grant), to Signor Cavallo, who was said to be willing to transfer that concession to this company. But all that was mere speculation. It was mere speculation that Signor Cavallo would obtain the concession at all, and secondly it was mere speculation that if he did get it he would transfer it to this company. All that could be said was that after the delay which had taken place Signor Cavallo had expressed his willingness—he had not entered into a binding agreement—to transfer it to the company if the Portuguese Government yielded the concession to him. It seemed to his Lordship that there was no reasonable prospect of any such concession being obtained, and, therefore, it was useless to continue this company.

His Lordship accordingly made a winding-up order in the usual form.

**Edison & Swan Co. and Others v. Bayley Bros.**—This case came on last Saturday, in the High Court of Justice, before Mr. Justice Stirling.

Mr. ASTON: Would your lordship allow me to mention what will be a very short matter. It is the case of the Edison & Swan Co. v. Bayley, in which I am instructed to say that it has now been arranged between the parties that an order shall be taken on the terms that the defendants shall submit to a perpetual injunction, pay the costs, and take a license. Then I apply to your lordship, supposing this meets with your approval, for a certificate that the particulars of breaches are reasonable.

Mr. JUSTICE STIRLING: I am not going to try whether the particulars of breaches are reasonable, or certify anything about it. I know nothing about it; but if you agree, I agree.

Mr. LEVETT: I appear for the defendants, my lord, and I cannot say that the particulars are unreasonable.

Mr. JUSTICE STIRLING: Very well then; take it by consent.

Mr. ASTON: If your lordship pleases.

**The Lightning Conductor Controversy.**—The *Western Electrician*, of Chicago, has published the writings of both Dr. Lodge and Mr. Varley on this subject. The editor, as is the case with Mr. Varley, cannot reconcile himself to the statements of Dr. Lodge, that "iron is as good or even better than copper for the purpose of conveying currents alternating with extreme rapidity," and that the extra resistance of a thin iron wire, used as a lightning conductor, has advantages over those offered by a thick copper rod. We draw the attention of both disputants to another article on the same topic which appeared in our last issue.

PROCEEDINGS OF SOCIETIES.

The Institution of Electrical Engineers.

“The Working Efficiency of Secondary Cells.” By W. E. AYRTON; C. G. LAMB, E. W. SMITH and M. W. WOODS, Associates. Read at Edinburgh, Wednesday, July 16th.  
(Continued from page 110.)

The following table gives a *resumé* of these results, all the discharges being made with 10 ampères until the P.D. fell to 1·8 volts per cell, and all the charges being made with 9 ampères until the P.D. per cell rose to 2·4 volts. Before each rest the cells were charged until the P.D. per cell was 2·4 volts.

Discharge.				Charge.				Percentage efficiency.	
Duration of discharge.	Ampere-hours.	Watt-hours per cell.	Number of curve	Duration of charge.	Ampere-hours.	Watt-hours per cell.	Number of curve.	Quantity.	Energy.

Cells now charged and discharged several times until brought to a steady working state.									
7 6	76	149·5	22	8 12	78·3	173·5	23	Ratio of first discharge after rest to first charge after rest. 91·1 81·1	
Cells now charged and discharged several times until brought to a steady working state.									
7 6	76	149·5	22	8 12	78·3	173·5	23	97·1	86·3

From the preceding table it will be seen that, in spite of the continued charging and discharging at the end of each rest, there is a steady falling off in the quantity capacity from 101·9 ampère-hours at the beginning to 76 ampère-hours at the end, and in the energy capacity from 201·7 watt-hours to 149·5 watt-hours. The quantity and energy efficiencies, 97·1 and 86·3 per cent. respectively, at the end are the same as at the beginning. Comparing the first discharge after each of the 16 days' rest with the last charge before the rest, there appears to be a loss of about 36 per cent. in the ampère-hours, and about 43 per cent. in the watt-hours; or, since the normal quantity and energy efficiencies for a discharge immediately following a charge are respectively 97 and 87 per cent., it follows that the rest of 16 days causes a loss of about 33 per cent. in the ampère-hours, and about 30 per cent. in the watt-hours, in addition to the losses that normally occur on a charging immediately followed by a discharging.

From all that precedes, it follows that the previous history of an accumulator produces an enormous effect on its efficiency. If, for example, an E.P.S. accumulator be over and over again carried round the cycle of being charged up to 2·4 volts per cell and discharged down to 1·8 volts per cell, the charging and discharging currents being the maximum allowed by the makers—viz., 0·026 ampère per square inch in charging, and 0·029 ampère per square inch in discharging—the “working efficiency” thus obtained may be 97 per cent. for the ampère-hours and 87 per cent. for the watt-hours. If, on the contrary, the cell be constantly charged up before being tested, then for the first few charges and discharges between the above limits, and with the same current-density in charging and discharging, even the energy efficiency may be as high as 93 per cent.; whereas, if the accumulator has been left for some weeks, then, although it was left charged, the energy efficiency for the first few charges and discharges will be as low as 70 per cent.

While, on the one hand, our tests show that continued rests

of a charged accumulator appear to be far more serious for the accumulator than we had previously imagined, the working efficiency appears to be higher than has hitherto been supposed, since we believe that about 84 per cent. efficiency in the watt-hours is all that the advocates of accumulators have claimed for them.

The smallness of the first discharge after a rest might be due either to a kind of electric short-circuiting and dissipation of the energy, or to some change in the character of the active material converting the energy perhaps directly into heat, or to some of the active material having become disconnected from the plates during the rest, and having fallen down to the bottom of the cell. The smallness of the first charge subsequently to the first discharge after the rest, shows that mere electrical leakage during that time has not been the cause of the loss of energy, while the steady increase in the storage capacity brought about by a series

of charges and discharges tends to show that rest brings about some change in the nature of the active material.

In all the tests in which the results are given in the preceding table, the charge and discharge were, as already stated, terminated when the P.D. per cell reached a fixed value; it is, therefore, possible that the apparent falling off in the capacity of the cells to store energy may be due to a change in the resistance of the cells produced by the rest. For a change in the resistance of the cells will change the terminal P.D. for a given current flowing through the cells without there being any necessary change in the storage capacity.

It is, therefore, interesting to study the variations in the shapes of the P.D. curves, 8 to 23. First, as regards the charge curves, 9 and 11 are convex everywhere to the axis of time, except just when the charging is commenced; whereas 13, the steady working charge curve after the second rest, rises much more rapidly when the P.D. cell is about 2·3 volts than is the case in the other two curves, then bends over and becomes concave to the axis of time. This peculiarity in curve 13 is, we notice, not very striking in the small reproduction of this curve in the text, but in the original curves, as plotted on large sheets of squared paper from the results of the tests, the difference between curves 11 and 13 is very noticeable.

The following list gives the time in hours and minutes from the commencement of the charging when the P.D. per cell reaches 2·2 volts:—

Curve 9 ... 7 h. 14 m. ... Steady working charge before rests.  
  “ 11 ... 7 h. 32 m. ...   “   “   “   after first rest.  
  “ 13 ... 7 h. 10 m. ...   “   “   “   “   second rest.  
  “ 15 ... 5 h. 36 m. ...   “   “   “   “   third rest.  
  “ 17 ... 3 h. 54 m. ... First charge after fourth rest.  
  “ 19 ... 5 h. 43 m. ... Steady working charge after fourth rest.  
  “ 21 ... 4 h. 50 m. ... First charge after fifth rest.  
  “ 23 ... 4 h. 40 m. ... Steady working charge after fifth rest.

It is clear, then, that the effect of a series of rests is to cause the P.D. to rise much more rapidly in subsequent charges, and the time curve rise of P.D. still remains unusually steep, although at the end of every rest there was a prolonged and uninterrupted series of charges and discharges.

Curves 16 and 20, which give the values of the P.D. for the first discharges after the fourth and fifth rest, show that for the first hour from the beginning of each of these discharges the P.D. rises instead of falling, as is the case in normal discharges.

If the rapid fall of P.D. at the commencement of a discharge be due to a disappearance of gases occluded in the plates, as some have supposed—or if, as Dr. Gladstone and Mr. W. Hibbert imagine, the charging of a cell causes the acid round the positive plate to become denser than that round the negative, and the mixing of the denser and less dense acid at the commencement of the discharge causes the P.D. to fall—then the absence of this fall at the beginning of a discharge after a long rest would be explained; but neither of these theories would apparently explain the rise of the P.D. obtained by us at the commencement of a discharge after a long rest. Indeed, the fact that it required two discharges and two charges after a long rest before the discharge curve (the third after the rest) acquired its normal form, tends to show that this rise of P.D. at the commencement of the first discharge after a long rest is due to some other cause.

Again, Prof. Duncan and Mr. H. Wiegand have shown in their communication that the diffusivity of the sulphuric acid into the plugs is greatest at the end of the charge, and least at the end of the discharge. Hence, if it be the diffusing out of the strong sulphuric acid from the plugs of the positive plate that causes the rapid fall of E.M.F. on breaking the charging circuit at the end of a charge (see figs. 3, 4, and 11), one would hardly expect that it would be at the end of the discharge, when the diffusivity of the acid in the plugs was a minimum, that the rise of E.M.F. on breaking the discharging circuit would be most rapid, but that numerous experiments have shown us to be the case. In fact, curve No. 8, fig. 11, shows that towards the end of the charge the E.M.F. falls from 2.298 to 2.274 volts in 20 seconds after breaking the charging circuit, and similar curves that we have drawn from our experiments on the time rise of E.M.F. on breaking the discharging circuit show that towards the end of the discharge the E.M.F. rises from 1.951 to 1.970 volts in 20 seconds, the latter rate of rise being almost exactly equal to the former rate of fall.

All the rests already referred to occurred when the cells were fully charged; but before these long rests took place the cells, when in their normal state, were on one occasion allowed to remain discharged for 34 minutes, with the following result:—

#### Cells in Normal State.

##### Time taken to complete—

Discharging	10 h. 10 m.	Charging	11 h. 38 m.
Next	„ 10 h. 12 m.	Next	„ 11 h. 37 m.
Next	„ 10 h. 11 m.	Next	„ 11 h. 37 m.
Cells here remained discharged for 34 minutes.			
First discharging after rest,	10 h. 15 m.	First charging after rest,	11 h. 50 m.
		Next charging after rest,	11 h. 42 m.

These results emphasise the fact that accumulators are damaged if left discharged even for a short time, and it was for this reason that during the whole of this investigation the cells were never left discharged for a longer time than was necessary to change over the connections from discharge to charge, except on this one occasion when it was desired to ascertain the magnitude of the change produced by leaving the cells discharged for a short time.

It is interesting to notice that the effect of discharging cells too low, or of leaving them discharged, is to increase the times required for the subsequent chargings, whereas the effect of leaving them charged is to diminish the times required for the next chargings.

#### VIII.—CHEMICAL ACTION.

Dr. Frankland has shown that probably the discharge of an ordinary accumulator is accompanied by the formation of one or other, or both, of the new lead salts which he has isolated, and which have the formulæ  $(\text{Pb}_2\text{S}_2\text{O}_{10})$  and  $(\text{Pb}_3\text{S}_3\text{O}_{14})$  respectively. And he concludes that, in view of the great difficulty of electrolytically splitting up the well-known white sulphate of lead  $(\text{PbSO}_4)$ , this sulphate is not formed in the ordinary discharge of the accumulator, and is only produced when the cell begins “to sulphate.”

Prof. W. Kohlrausch and C. Heim show in their paper already referred to that the observed variations in the specific gravity of the liquid during charge and discharge agree well with the very simple chemical actions—

##### Charge.

Positive plate—

Negative plate—

##### Discharge.

Positive plate—

Negative plate—

It is to be noticed, however, that the falling off in the specific gravity during discharge is merely a test of the amount of  $\text{H}_2\text{SO}_4$  that is converted into  $\text{H}_2\text{O}$ , and affords no criterion as to what sulphate of lead is formed by the  $\text{SO}_3$  liberated.

During our investigation we observed the variation in the specific gravity of the liquid during about 100 charges and discharges, and the mean of this large number of the fairly consistent results that we obtained showed that, with the accumulators we were testing, the variation in density per ampere-hour was about 0.000232. This result is probably right to within 5 per cent., for our hydrometer would read accurately to about 0.001, which is about 5 per cent. of 0.03, the total change in specific gravity observed during the discharge; and, therefore, as each result is correct to something like 5 per cent., the mean of a hundred results will certainly be correct to within 5 per cent.

On referring to tables of the density of dilute sulphuric acid, we find, by plotting the results, that between the limits we are concerned with—1.2 and 1.17—the change of density is directly proportional to the amount of  $\text{SO}_3$  taken from the solution; and, further, that to produce a change in density of 0.01 at 15° C., it requires that 1 gramme of dilute sulphuric acid of density 1.2 should give up 0.01268 of a gramme of  $\text{SO}_3$ . And as the liquid in each cell weighed about 10,490 grammes when the cell was charged and the density 1.2, it follows that the weight of  $\text{SO}_3$  liberated per ampere-hour in each cell, when calculated from the variation in the specific gravity, must equal—

$$\frac{0.000232}{0.01} \times 0.01268 \times 10,490 \text{ grammes,}$$

or

$$3.086 \text{ grammes.}$$

Further, the electro-chemical equivalent of  $\text{SO}_3$  is 0.000414 grammes per coulomb; and since lead sulphate is formed on both the positive and negative plates during the discharge, the weight of  $\text{SO}_3$  taken out of the liquid per ampere-hour, when calculated from the electro-chemical equivalent of  $\text{SO}_3$ , must be

$$2 \times 3,600 \times 0.000414 = 3.041 \text{ grammes.}$$

These two results show a close agreement. At the same time, it is to be noticed that not merely does the amount of  $\text{SO}_3$  liberated per ampere-hour come out somewhat higher when calculated from the mean change in the specific gravity than when calculated from the chemical equivalent, but the same result is obtained for each separate set of tests.

Mr. G. H. Robertson, working in Dr. Armstrong's laboratory, was so good as to analyse the sediment that fell to the bottom of the cells during the early part of the investigation, when in the discharges the P.D. was allowed to fall to 1.6 volts per cell. The mixture was found to contain—

An indication of uncombined metallic lead,

A trace of antimony,

40.95 per cent. of combined lead	} i.e., 47.3 per cent. of $\text{PbO}_2$
6.35 „ „ oxygen	
34.63 „ „ lead	
5.36 „ „ sulphur	
10.75 „ „ oxygen	} i.e., 50.74 „ „ $\text{PbSO}_4$
	98.04

so that 1.96 per cent. consisted of metallic lead, antimony, and dirt.

The composition of the sediment showed a close approximation to  $\text{PbO}_2$ ,  $\text{PbSO}_4$ , which consists of—

44.08 per cent. of $\text{PbO}_2$
55.92 „ „ $\text{PbSO}_4$

$\text{PbO}_2$ ,  $\text{PbSO}_4$ , in fact, contains—

76.33 per cent. of Pb
5.91 „ „ S
17.76 „ „ O

and the sediment contained—

75.58 per cent. of Pb
5.37 „ „ S
18.05 „ „ O

Dr. Frankland's salts may be represented as  $\text{PbO}_3$ ,  $2(\text{PbSO}_4)$  and  $2(\text{PbO})$ ,  $3(\text{PbSO}_4)$  respectively, whereas the analysis of the deposit in our cells showed that it was certainly neither of these lead salts, but, instead, had almost the exact composition of  $\text{PbO}_2$ ,  $\text{PbSO}_4$ .

In spite of accumulators with pasted plates having been in use now for nine years, the chemical action that takes place during the different stages of the charge and discharge has only been conjectured, and, odd as it seems, no decisive experiment appears to have been made to settle this much debated question. Various analysis have been made by different chemists of salts of lead acted on in certain ways with sulphuric acid, but apparently not of actual accumulator plates in action. We are therefore now, with the assistance of Mr. Robertson, making a complete investigation of the chemical state of the plugs of both the positive and negative plates at all stages of the charge and discharge of an 1888 E.P.S. type of accumulator in good condition. As this investigation, however, involves the chemical analysis of

a large number of specimens, it will take some time yet to complete.

In order to observe what changes took place in the temperature of the cells during charge and discharge, the temperature of one of the cells under test was observed from time to time, as well as the temperature of the air and the temperature of an adjacent cell through which no current was being passed. The following temperature results, which were obtained during the steady discharges and charges after the first rest of ten days (curves 10 and 11), are a sample of the observations taken. The discharge in each case commenced directly the P.D., in charging, had reached 2·4 volts per cell, and the charge in each case commenced directly the P.D., in discharging, had fallen to 1·8 volts per cell.

H. Wiegand in America, and described in their joint investigation already referred to.

From the last table we see that the rise of temperature of the cell during charging may, after allowing for changes of temperature of the room, be either about 1·3° C. or 0·77° C., while the fall of temperature during discharging may have either of the two preceding values. It is further interesting to notice that the rise of temperature during the charging has the higher or the lower of these two values, according as the fall of temperature during the previous discharge had the higher or the lower value.

On plotting the differences between the temperatures of the working and the idle cell, and the corresponding times given in the last table, we obtain the dotted line, 24 (fig. 8), for the time fall of temperature during the first and third discharge, curve 25

Date.	Time.	Cell under test.			Temperature of			Time from beginning of discharge or charge.	Difference between temperature of cell under test and temperature of idle cell.	Rise or fall of temperature during a complete discharge or charge, compared with temperature of idle cell.

Variation of temperature during discharge and charge.

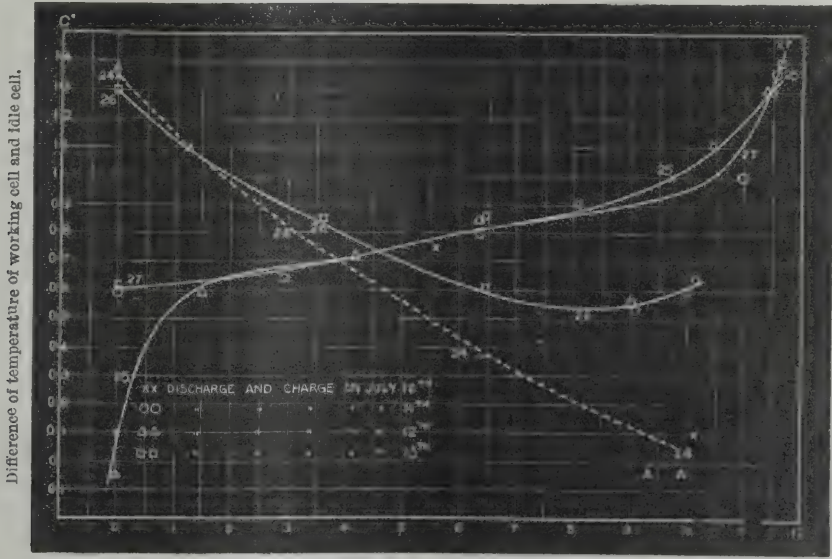

FIG. 8.

From the preceding table we see that, while during the charge the cell rises in temperature, during discharge, on the contrary, it actually falls; hence, in spite of the production of heat due to resistance, the cell is actually cooler at the end of a discharge than at the beginning—a result possibly due to the splitting up of the sulphuric acid during the discharge. This cooling of accumulators during discharge, which we noticed early in our experiments, was also observed at about the same time by Prof. Duncan and

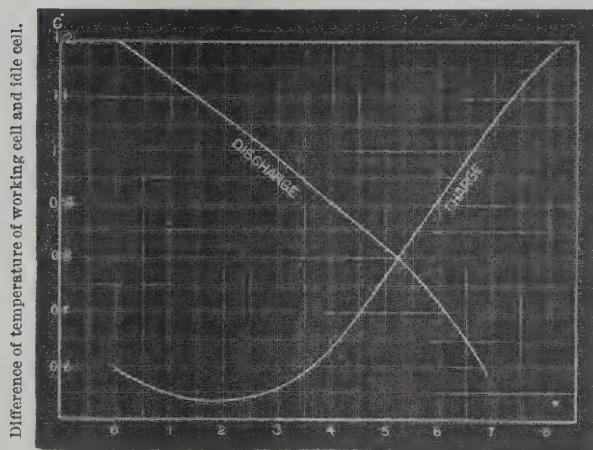

for the time rise of temperature during the first and third charge, curve 26 for the time fall of temperature during the second and fourth discharge, and curve 27 for the time rise of temperature during the second and fourth charges. 24 is dotted, since temperature readings were only taken at the beginning and end of the first and third of these discharges. In the case of the second and fourth of the discharges here referred to, as well as in all the four charges, several observations of temperature were made.

From the curves it appears that towards the end of the discharge and at the beginning of the charge, one or other of two things may happen—either the temperature in the discharge may go on falling, as in the dotted line, 24, or it may begin to rise again, as in 26; whereas, in the charge, either the temperature at the beginning may rise considerably, as in curve 25, or it may only increase slightly, as in curve 27.

It would therefore appear that during the latter part of the discharge one or other of two chemical actions can take place; and these two actions have, for some reason or other, taken place alternately in the four discharges under consideration. But, curiously enough, these four discharges—which took place on July 10th, 11th, and 12th, 1889—occurred with extreme regularity; so that when the time curves were drawn, even on a large scale, for each of these discharges, they coincided exactly and produced a single curve, which is shown, greatly reduced, as curve 10 on the sheet of curves given in the earlier part of the paper. And, similarly, for the four corresponding charges the four time curves all coincided exactly, producing a single curve, which is shown, greatly reduced, as curve 11 on the same sheet. It, therefore, seems as if one or other of two chemical actions might take place during the latter portion of the discharge and during the earlier part of the charge, and yet, curiously enough, when the current is kept absolutely constant the time variation of the P.D. is exactly the same, no matter which of these two chemical actions takes place.

About a year later another set of continuous temperature observations was made for many days and nights with the same cells, the current in discharging and charging being, as before, 10 and 9 amperes respectively. The higher P.D. limit was, as before, 2.4 volts per cell, but the discharge was in each case in this second set of continuous discharges and charges, stopped at 1.9 instead of 1.8 volts per cells. As the regulation of the current day and night was in these later experiments in 1890 effected by hand, it was not kept quite as constant as when the automatic regulator was

Variation of temperature during discharge and charge.

Time in hours from beginning of discharge or charge.

FIG. 9.

employed. Hence the time curves for the excess temperature in discharging and charging, when plotted, were not found to be as regular as in the previous case. But they were quite regular enough to give the general shape of the sets of temperature curves for discharge and charge which are shown in fig. 9.

It will be observed that in these experiments not merely does the excess of the temperature of the working cell over that of the idle cell fall during the discharge, but it actually continues to fall at the commencement of the charge.

The times of discharging and charging are less than those given for curves 10 and 11, partly because the P.D. was not allowed to run down lower than 1.9 volts per cell in the later observations, and partly because the times of discharging and charging had been diminished by the continued experimental rests to which these cells had been subjected in a charged state during 1889.

The mean temperature of one of our cells is during charging and discharging, roughly,  $0.7^{\circ}\text{C}$ . higher than that of the air; and experiment shows that if one of the cells experimented on be warmed up by a portion of the ordinary dilute sulphuric acid being replaced by warm sulphuric acid of the normal density, the cell will, after all parts of it have acquired a uniform temperature, fall in temperature by  $0.2443^{\circ}\text{C}$ . per hour. Of course, during such an experiment no current is allowed to pass through the cell, nor should any current have passed for hours before the heat emissivity of a cell is determined, otherwise a wrong value of the emissivity may be obtained by local action in the cell generating or absorbing heat during the experiment.

Hence, if  $\kappa$  be the heat capacity of the cell,  $0.7 \times 0.2443 \times \kappa \times 21\frac{1}{2}$  calories (gramme, centigrade) will be lost by radiation and convection during the  $21\frac{1}{2}$  hours of charging and discharging. Now the weights and specific heats of the component parts of one of the cells under test are:—

	Weight in Grammes.	Specific Heat.
Dilute acid, sp. gr. 1.9	10,490	0.792
Lead and lead oxide...	12,987	0.0315
Glass	3,402	0.198

Hence,  $0.2443 \kappa$  equals 2,295 calories, and the loss of heat in charging and discharging equals 34,520 calories. The total watt-hours given to a cell in charging was 228.2 (see curve 11 for the working results obtained with the cells after the first rest of 10 days), therefore the energy in calories given to the cell was  $0.24 \times 228.2 \times 3,600$ , or 197,200 calories. Hence, in consequence of the cell being slightly warmer than the air during charging and discharging, there is a loss of energy from radiation and convection equal to about 17 per cent. of the energy put into the cell, and this is more than sufficient to explain the total loss observed in the energy efficiency experiments, which amounts to only about 13 per cent. Indeed, it would almost seem as if a portion of this heat radiated must be supplied by an actual slow consumption of the material of the cell; so that, in addition to the reversible oxidation and deoxidation of the material, which is the characteristic of the secondary cell, there was a certain amount of non-reversible oxidation, which is the characteristic of the primary cell.

The loss of energy in consequence of the current having to overcome the resistance of the cell is of far less importance than the loss of energy due to the actual continuous radiation and convection from the cell, which is slightly warmer than the air. For the mean resistance during discharging of one of the cells experimented on may be taken as  $0.004$  ohm (see Section IX., Resistance, figs. 12 and 13), and the mean resistance in charging as  $0.0045$  ohm. Hence, during the normal 10 hours of discharge with 10 amperes there will be generated,

$$0.24 \times 10^2 \times 0.004 \times 10 \times 3,600, \text{ or } 3,456 \text{ calories,}$$

and during the normal  $11\frac{1}{2}$  hours of charge with 9 amperes,

$$0.24 \times 9^2 \times 0.0045 \times 11\frac{1}{2} \times 3,600, \text{ or } 3,621 \text{ calories.}$$

Only, therefore, 3,456 calories need be dissipated during the discharge of a cell, and 3,621 during the charge, in consequence of the heat produced by the current overcoming resistance; and to dissipate this amount of heat it would only be necessary that the mean temperature of the cell should exceed that of the air by about  $0.14^{\circ}\text{C}$ ., or only about one-fifth of the actual mean excess. Whereas what actually takes place is that during discharge about 16,060 calories are dissipated by radiation and convection; and, further, the cell cools down, possibly in consequence of the splitting up of the sulphuric acid, and from 6,000 calories in some experiments to 12,000 in others are thus absorbed. During the charge these 6,000 or 12,000 calories reappear warming up the cell, and, in addition, about 18,460 calories are dissipated by radiation and convection.

In order, then, to improve accumulators, what has to be especially sought for, and, if possible, then prevented, is that chemical action which keeps the mean temperature of the cell about  $0.7^{\circ}\text{C}$ . above that of the air. This chemical action is very possibly quite distinct from the reversible one which necessarily accompanies the storing up of the electric energy and its subsequent liberation.

#### IX.—RESISTANCE.

The resistance in ohms of an accumulator when charging and discharging is given respectively by

$$\frac{V - E}{A}, \text{ and } \frac{E - v}{A},$$

where  $v$  is the P.D. in volts at the terminals when a current of  $A$  amperes is passing, and  $E$  is the E.M.F. of the accumulator at the moment  $v$  is measured. To measure  $E$  the main circuit is broken, and the P.D. observed as quickly as possible. On breaking the circuit, however, the deflection of the voltmeter does not sharply change from the value that measured  $v$  to another definite value that measures  $E$ ; but, on the contrary, as seen from fig. 4, in consequence of the fall of the E.M.F. of an accumulator on breaking the charging circuit, and in consequence of a similar rise in the E.M.F. on breaking the discharging circuit, the voltmeter deflection continues to vary for several minutes after the circuit is broken. Hence the value of  $E$ , measured by a voltmeter which is not infinitely dead-beat, must be too small during charging, and too large during discharging; and consequently, since the above formulæ for the resistance are only true when  $v$  and  $E$  are the simultaneous values of the P.D. at the terminals of the accumulator and of its E.M.F., it follows that the resistance has hitherto been measured too large both in charging and discharging.

The magnitude of the error that has been thus made in different experiments depends, of course, on how dead-beat a voltmeter was employed, and, consequently, on how long a time was allowed to elapse between the breaking of the main circuit and the taking of the reading. For example, we find that towards the end of the charge with the normal current of 9 amperes the E.M.F. varies about 1 per cent. in 20 seconds after the circuit is opened. Now, as the difference between  $v$  and  $E$ , which measures the resistance, is only of the order  $0.1$  volt when it has its maximum value during the normal charge or discharge—that is, of the order 4 per cent. of  $E$ —it follows that an error of 1 per cent. in the measurement of  $E$  would make an error of about 25 per cent. in the measurement of the resistance.

To measure the resistance accurately, we ought to be able to measure the difference between  $v$  and  $E$  to one-thousandth of a volt, and, therefore, as  $E$  is about 2 volts, the voltmeter must be very sensitive, with a long, open scale, and the needle must move through a considerable angle; whereas, in consequence of the rapid variation in  $E$ , the voltmeter must be very dead-beat—a condition almost incompatible with a long range and great sensibility.

(To be continued.)

THE TELEPHONE IN SWEDEN AND  
NORWAY.

In February of this year a report on the telephone and its extension at Stockholm and Gothenberg was presented to Parliament, and now another, referring to the telephone system at Christiania, has been printed. From this report we learn that the International Bell Company was the first, in 1880, to establish telephonic communication at Christiania. In 1881 a "Telephone Association" entered into competition with it, and obtained by the end of that year 224 subscribers, against 462 subscribers to the Bell Telephone Company. The two telephone systems continued to operate in competition with each other until the end of December, 1885, when the Bell Company had already fixed 995 apparatus, and the Telephone Association 634, representing an aggregate total of 1,629 subscribers. Their amalgamation into one company was at last effected by pressure on the part of the municipality, which prohibited the Bell Company and the Association from putting up any more wires separately.

On the 1st January, 1886, the Christiania Telephone Company superseded the two original companies, which were indemnified on the following terms, namely:—

Bell Company (its property was valued at £8,333) ... ..	£13,384
Telephone Association (valuation of property, £4,444) ... ..	7,000
Total ... ..	£20,384

The capital of the Christiania Telephone Company is 500,000 kroner (about £27,890), raised on 2,500 shares of 200 kroner (£11 2s. 3d.) each. The dividend declared for 1889 amounted to 5 per cent. on that capital, and the shares now stand at 25 per cent. premium. The number of subscribers on the 1st January, 1890, was 2,133, and their increase, expressed as a percentage, has been as follows:—

	Per cent.
1886 ... ..	7
1887 ... ..	17½
1888 ... ..	33
1889 ... ..	53½

The total number of apparatus under the control of the company at the end of 1889 was 2,405, of which 68 belonged to subscribers.

The following are the regulations under which telephones are established and worked in Norway:—

By a Royal decree issued in 1884, a law of July 31st, 1859, regulating the construction and maintenance of railways and telegraph lines in Norway was made applicable to the establishment of telephonic communication. In virtue of that decree permission has been granted to companies to establish telephonic communication either between towns and surrounding districts, or in rural districts between such districts, or with neighbouring towns, the licenses remaining severally in force for a period of five years. No exclusive right is given to individual companies, but no licenses are granted to competing companies before all the local authorities have been consulted. A royalty is payable under a license only when the telephonic communication has been established between two or more places where telegraph stations are maintained by the State. The royalty annually payable is then calculated on a scale proportionate to the receipts from telegraphic correspondence between the points in question, and is generally fixed at one-half or one-third of such revenue. The licenses contain no conditions as to the purchase of the telephone exchange systems by the State, either within the periods for which they have been granted or on the expiration of non-prolongation of a license. The State allows telephone companies to place exchanges in connection with telegraph offices at their own cost, and without any responsibility on the part of the telegraph service for secrecy or accuracy of transmission. No charge is made to companies for such connection. A few companies have erected on their lines public telephone stations, to which telegrams can be sent from any telegraph office in the country. The companies are allowed to charge for the transmission of the telegrams sent by their lines a general rate of 0.50 kroner (6½d.), regardless of the number of words. The tariff books of the State telegraphs specify this rate, and give the names of the telephone stations.

An exception, however, from this arrangement has been made in regard to the connection of a couple of places, where there had previously been State telegraph offices, with a private telephone in a neighbouring town. In these cases the State has given a subvention once for all, on condition that call offices should be provided, no extra charge made for telegrams, and a moderate tariff fixed for other use of the telephone from the points in question to the central office. The telephones established in certain rural districts by the State are regarded as part of the telegraph system, and are to some extent worked on telegraph lines that are utilised by the telegraph during only part of the year. In such places contracts are made for certain short periods of years with the interested parties, under a communal guarantee to the effect that an efficient clerk not connected with any mercantile business will be kept at the cost of such parties, and that the contractors will undertake the entire working of the telephone station, including free accommodation, lighting, heating, and the services of a messenger. They are granted a small subvention not exceeding 200 kroner (£11 2s. 3d.) per annum, and a small return of the

charge for each conversation through the telephone is made to them. Telegrams are in such cases free of extra charges. In a couple of valleys, through the State telegraph lines run, telephone wires have been erected on the telegraph poles in order to connect road posting stations with the nearest telegraph office. These offices are all established on the principle just mentioned, except that the contracts remain in force for 10 years, and the contractors receive no subvention from the State, which has defrayed the cost of the lines and erection of the telephone stations, and which undertakes the repair of the lines and the keeping of the apparatus in order.

With regard to the description of telephone generally used, the gentleman sending the report to the Foreign Office (Mr. T. Mitchell) says it is the ordinary apparatus with magneto-electrical call bells. Relatively few apparatus of the electro-magnetic type, with which signals are given by battery current, are in use. The transmitters are generally on Blake's, and only a few on Ader's system. The receiver is either a Bell (one pole), or a Siemens (two pole) telephone. At the exchanges in Christiania and Bergen the central apparatus consist of multiple switchboards, but at all other places of switchboards of older construction. The apparatus are partly patented, and the State has no right to use or make them. The cost of a complete telephone, comprising one transmitter and one receiver, ranges, according to decorative finish, between 72 kroner (£4) for a magneto-electrical apparatus from the *Elektrisk Bureau* at Christiania, or from Ericsson at Stockholm, and 56 kroner (£3 2s. 3d.) for Bell Blake's apparatus, from the Bell Telephone Manufacturing Company at Antwerp. The average cost of maintaining in working order a complete telephone (transmitter, receiver and battery, or magneto-electrical call bells) is reckoned to be from 15 to 20 kroner (16s. 8d. to 22s. 3d.) per annum. The wires used for the State telephone lines are all of silicium bronze, of a gauge 2 mm. in diameter. Except at Christiania and Bergen, where silicium bronze wire 1.25 mm. in diameter is partly applied, the private companies use for the exchanges Swedish iron wire of 22 mm. in diameter. At Christiania aerial cables, containing 27 or 52 wires, are used in the vicinity of the central station. For inter-urban lines iron wire 3 mm. in diameter is used on short distances, and silicium bronze from 1.5 to 2.5 mm. in diameter on longer ones. The average cost per annum to the companies of maintaining 1 kilom. of wires is calculated to be from 10 kroner to 15 kroner (11s. 1½d. to 16s. 8d.). Private inter-urban wires are not allowed to be erected on the State telegraph poles. The State telephone wires are erected on the telegraph poles on the English system, which has been effective in preventing induction. The average cost of poles varies according to the place where the construction of lines takes place. The State pays for the best poles, 25 feet long, 6 inches in diameter at the top, with 3 to 4 inches heart, on an average 30 kroner (33s. 4d.) per dozen. The prices of poles supplied to the Christiania Telephone Company are as follows:—For pine 25 feet in length, 20 kroner (22s. 3d.); for fir, 22 kroner (24s. 6d.) per dozen; for pine, 50 feet in length, 70 kroner (77s. 9d.); for fir, 85 kroner (54s. 6d.) per dozen. The cost of wire is the ordinary market price. Silicium bronze wire, more especially, has been very fluctuating of late in price. The porcelain insulators for the State telephone lines (the type being the same as that used for telegraph lines) cost about 0.50 kroner (6½d.) a piece. The cost of the double insulators used by the private companies is about 0.17 kroner (2d.). The cost of labour in the erection of the State telephone lines is the same as that for telegraph lines, and varies greatly according to the more or less mountainous ground to be passed. The average cost is about 80 kroner (88s. 11d.) per kilom. The private companies estimate the cost of labour at about 30 kroner (33s. 4d.) along the roads. On the houses it varies very much. The average may be said to be 25 kroner (27s. 9d.). It may here be remarked that the exchange and office work of the Christiania Telephone Company is principally performed by females. The annual charge for the use of a telephone in connection with an exchange varies greatly in the different companies: in the mutual societies, where the subscribers are owners of the lines, the apparatus, and the central station, the charge is from 30 kroner (33s. 4d.) to 60 kroner (66s. 8d.) per annum. When the companies are founded on shares, the annual charge is within the first circle (generally 1½ kiloms. from the central station) from 50 kroner (55s. 7d.) to 100 kroner (111s. 2d.), and is increased for greater distances. The Christiania Telephone Company, founded on shares, make an annual charge for the 1st circle of 80 kroner (£4 8s. 11d.), with an addition of 7.50 kroner (8s. 4d.) for each half kilom. beyond. The subscribers of telephone companies founded on shares are generally bound for one year. The mutual societies have not bound themselves to give any compensation for lines and apparatus belonging to former members. On the State telephone lines there is no special charge made for the telephoning of telegrams. For conversations by telephone the charge is 0.20 kroner (2½d.) to 0.50 kroner (6½d.) for five minutes. Public call offices are provided only in a few towns. At Christiania they are generally established in the house of a subscriber (generally a shop), who receives a remuneration of 30 per cent. of the revenue, the charge for each conversation being 0.10 kroner (1½d.), whether to subscribers or non-subscribers. All the telephone exchange wires are aerial and single. The existing trunk wires between towns (communications inter-urbaines) are all maintained by the companies, namely, between the following places:—Christiania-Gjøvik, annual royalty to the State 300 kroner (£16 13s. 4d.), distance about 110 kilom., charge for five minutes' conversation 0.50 kroner (6½d.). Christiania-Hønefos, distance about 60 kilom., charge for five minutes' conversation 0.50 (6½d.). Drammen-Kongsberg. Chris-

tiania-Moss, annual royalty to the State 2,000 kroner (£111 2s. 3d.), distance about 60 kilom., charge for five minutes' conversation 0.50 kroner (63d.) Skien-Porsgrund, royalty to the State 500 kroner (£27 15s. 7d.). Porsgrund-Langesund, royalty to the State 200 kroner (£11 2s. 3d.) The State has the right to erect poles and wires on public roads and private property against full compensation for value and damage under the provisions of the law of July 31st, 1859. Companies have no such legal right, but the local authorities and the landowners generally give permission to that effect without making any charge, the establishment of a telephone exchange being in the interest of the local inhabitants. The State telephone lines are regarded financially as part of the telegraph system, and the expense of their maintenance is expected to be covered by the revenue they yield. The total number of telephone exchanges (all private) in Norway is 30. The number of subscribers to each exchange, and the total number of inhabitants in each town or locality are shown in a statement hereunto annexed. The Government does not interfere in the establishment of private telephone systems to a greater extent than may be necessary in order to avoid collision between the different companies, and in order to protect the interests of the State telegraphs. In the latter respect the State only requires remuneration for a decrease in the number of telegrams exchanged between telegraph offices, contingent on the establishment of telephone lines between the same places. The system on which telephones are established and worked in Norway seems to be well adapted to a country of which the population is spread over a large extent of territory. The telephone exchange systems have, more especially in the two or three last years, grown rapidly—first, within the limits of certain towns or parishes, and then expanding to the surrounding districts or parishes. The telephone is being more and more regarded as a convenience of household necessity. What bells are for calls inside a house, the telephone is for outside calls; and as there is no charge for royalties, &c., included in the cost of establishing an exchange, the subscription rate can be made so low that the acquisition of a telephone apparatus is within the reach of moderate means.

There are three appendices to the report, the third of which is as follows:—

The Number of Subscribers to each Telephone Exchange in Norway is:—

	Subscribers.	Inhabitants.
Christiania ... ..	2,133	140,000
Bygdø ... ..	35	Rural districts. The Christiania Telephone Company.

NEW PATENTS—1890.

10939. "Electric lamp holder and switch for capped incandescent lamps." C. McDONALD. Dated July 14.

10941. "Improvements in electrical contacts or collectors of electricity for railways and other purposes." F. WYNNE. Dated July 14.
11017. "Improvements in or relating to conduits and permanent way for electric railways." W. P. THOMPSON. (Communicated by J. Lynch, United States.) Dated July 15. (Complete.)
11042. "Improvements in electric thermometers and thermographs." J. W. GOOCH, C. A. BAKER and W. WHITE. Dated July 15.
11045. "Improvements in printing telegraphs." W.W. TAYLOR and E. M. LEAVENS. Dated July 15. (Complete.)
11052. "Improvements in telegraph receivers." C. LANGDON-DAVIES. Dated July 15.
11061. "Improvement in electric railway switches." H. H. LAKE. (Communicated by W. D. Swart, United States.) Dated July 15.
11065. "Improvements relating to the impregnation of organic, fibrous, and cellular matter, by means of an electric current, and apparatus therefor." G. A. ONCKEN. Dated July 15.
11070. "Improvements in and connected with electric measuring instruments, incandescent lamps, telephone transformers, electrically worked organs, and materials for jellygraph copying and printers' rollers." J. SWINBURNE. Dated July 16.
11130. "Improvements in insulating compositions for electrical purposes." A. N. FORD. Dated July 17.
11187. "Improvements relating to the manufacture of articles by electro-deposition, and to compositions for use in such manufacture." A. W. ARMSTRONG. Dated July 17.
11193. "Improvements in electrical switches." J. TRECZIOK. Dated July 17.
11240. "Improvements in electric arc lamps." J. Y. JOHNSON. (Communicated by L. Bardon, France.) Dated July 18. (Complete.)
11263. "Improvements in wall sockets for temporary electric connections." J. M. M. MUNRO. Dated July 19.
11272. "An improved ceiling rose for the suspension of electrical fittings." T. R. ANDREWS and T. PREECE. Dated July 19.
11312. "An improved device for maintaining electrical connection between separate railway trains." J. P. BAYLY. (Communicated by A. Baker, United States.) Dated July 19.
11319. "Improvements in apparatus to be used for electric welding." H. HOWARD. Dated July 19.
11327. "Improved electrically operated stamping and crushing machines." C. T. J. VAUTIN. Dated July 19.

ABSTRACTS  
OF PUBLISHED SPECIFICATIONS, 1889.

4125. "Improvements in holders for incandescence electric lamps." W. O. ROOPER. Dated March 8. 8d. The holder consists of a cylindrical body made of vulcanite fibre, ebonite, china, or other suitable non-conducting material, to the outer surface of which are attached two or more spring clips which embrace the neck of the lamp bulb or globe, and two metallic attachments fitted with binding screws for connecting the leads to the lamp wires. The upper external part of the body of the holder is screw threaded to receive a screwed cap of brass or other suitable material, having a hole in the centre of the top thereof, through which the leads or conducting wires are passed on their way to the aforesaid metallic attachments. 5 claims.
5976. "An improved automatic electric alarm clock." A. LEYLAND. Dated April 8. 8d. Has for its object that of providing an electric alarm that will ring until stopped, and re-set itself ready for being operated, according to the time intended by the alarm dial. 4 claims.
6384. "Improvements in and relating to electric switches." A. A. GOLDSTON. Dated April 13. 8d. Claims:—1. In an electrical switch, the combination of a switch lever provided with two conducting pieces insulated from each other and adapted to be permanently connected to the main circuit, and two pairs of contacts, one of which pairs is designed to be connected with the terminals of the circuit to be introduced, while the other pair is in electrical connection, all arranged and operating substantially as described. 2. An electrical switch adapted to cause the main line current to pass through an "introduced" circuit or through a short circuit, the arrangement being such that when the current is passing through the short circuit the terminals of the "introduced" circuit will be out of electrical contact with the switch or with themselves, substantially as described. 3. The manufacture and use of the improved electrical switch described and illustrated in the drawing.
8157. "Improvements in switches for electric signalling apparatus." L. SELLNER. Dated May 16. 8d. Relates to switches by means of which any desired lamp from a number of white and coloured or continuously and intermittently lighting electric incandescent lamps can be interposed into the circuit of an electric current generator, in order to give a signal, while, at the same time, an equal number of other lamps, provided for maintaining in the circuit unvariable resistance, are put out of circuit. 6 claims.

18638. "Improvements in the mode of driving electrical vehicles." A. DICKINSON. Dated November 21. 6d. The gear is all mounted in an extra frame, one end of which is pivoted upon one of the bogie axles, and the other end is so mounted in a radial axle box or horn plates that this end of the frame is free to move upwards and downwards, but its liberty is governed by spring arranged to check its movement within certain defined limits. The central bearing of this moving end of the frame is circled so as to permit each of the two rail wheels to move unevenly without interference with the frame. The motor is mounted on a shaft near the centre, in suitable bearings, and transmits the motion through helical gear and counter shafts to the bogie axle on each side. 3 claims.

## CORRESPONDENCE.

### Electric Light Fittings.

With reference to your note of the electric light fittings at the Hotel Metropole, Brighton, we are much surprised that Messrs. Benham and Frowde should have informed you so incorrectly of the true facts of the case.

The electric light fittings at this hotel were supplied by at least four different firms, none of whom were responsible for the designs, which were supplied by Mr. Alfred Holland, one of the directors. Our firm supplied the fittings for the entrance and main halls, drawing rooms, library and reading room, smoking room, staircase, principal corridors, standards for 42 principal bed rooms, and fittings for all bath rooms and many offices.

It can hardly be said, therefore, that the electric light fittings have been supplied by Messrs. Benham and Frowde, and we are informed that the above form certainly the majority of them.

B. Verity & Sons.

July 26th, 1890.

### Steno-Telegraphy.

In your paragraph on "steno-telegraphy," published in your number of July 18th, p. 71, you compare the latest form of Wheatstone's automatic instrument, such as now in use in England, and M. Cassagne's system. It is, nevertheless, a fact that this latter system—perfectly simple and reliable as it is—enables a single operator to punch his tape at a rate of speed not hitherto attained in telegraph work (100 orthographic words, or 200 shorthand, *i.e.*, phonetically spelt words, per minute).

This speed can be maintained for hours at a stretch. Moreover, the message is received in type.

This system is the only one, so far, which enables four persons, at the outside, to transmit 400 words per minute on a single wire. The difference between these four persons and the regular army of operators required for the same result with the Wheatstone system, is too important to be looked over by impartial minds.

The commercial aspect of the question can be summed up as follows:—

With two operators at each end of a line wire (four in all), M. Cassagne's instruments can send 400 words per minute. What would be the number of words sent by the Wheatstone in the same time, and with the same number of men?

L. H. Despeissis.

3, Rue du Mont Thabor,  
Paris, July 28th, 1890.

### Brush v. King. Brown & Co.

This judgment does not in the least surprise me, but I must confess to being greatly amused with the idea of so much money being wasted in lawyer's fees.

I have come to the conclusion that there is scarcely one valid patent in existence. This is not merely a hastily formed and speculative opinion, but is based on a most careful study of the patent specifications; a

study to which I have devoted my spare time during the last six or seven years.

Nothing can be further from my thoughts than to insinuate that any of the existing patents have been obtained by those who were not *bonâ fide* inventors. Those patentees have doubtless acted in perfect good faith, and without the least desire to appropriate the lapsed or uncompleted patent of their predecessors. But the fact remains that very many inventions on which patents are now held without dispute, are anticipated, and set forth in former specifications with far clearer language than Mr. Varley used.

It is obvious that my remarks are to be taken in a broad and general sense. Every invention must necessarily be new at some time or other; but it certainly seems very curious that many of the existing patents are to be found very exactly described in the specifications of twenty or more years back.

C. Purcell Taylor, D.Sc.

July 28th, 1890.

### Secondary Battery Manipulation.

I have not the slightest doubt that Mr. Barber-Starkey's communication on the above subject, which appeared in a previous issue, will be read by many with interest, and, probably, by himself and others, may be considered new; but this really is not the case, as the methods communicated by him are neither new nor novel, nor can they be considered any improvement in storage battery manufacture, according to present knowledge; in fact, this ancient method, as suggested by Mr. Starkey, is rather a detriment to success than otherwise, as I well know from practical experience, having as far back as 1882 manufactured, in conjunction with Dr. Woodward, the inventor of the Woodward system, storage batteries in numerous shapes and forms, many of which I have still by me as historical productions, showing some of the early work carried out in connection with this section of the industry; and, singular to say, amongst them is a cell in which the plates are divided by a compound packing of pulverised cocoanut fibre, boxwood, gypsum, &c., which was used by us as a separator of the lead plates. We also used many other forms of insulation, some of which were made from xylonite, Blake's embonita, vegetable ivory, and other fibrous materials suited for this purpose, which batteries, in various forms of manufacture, were publicly exhibited by my late firm at the "Engineering and Metal Trades Exhibition," held at the Agricultural Hall in the year 1883, and other exhibitions of more recent date; and as a record of experimental research, I may say that in our experiments we found that pulverised cocoa-nut fibre was the best adapted for the purpose we then had in view, the manufacture of a compact form of spongy lead plate which could be closely packed side by side without fear of buckling or short-circuiting the cell when used for traction work; but, after many experiments, this type of cell was abandoned by Dr. Woodward for his improved method, as now universally adopted by all makers of the Woodward cell, thousands of which are in daily use, doing good, active work in the United States of America, Canada, and other parts of the world; and in all probability in the near future a like effect may follow in this country. I may also say that I explained Mr. Starkey's proposed plan to Mr. Joel, and many others in the trade, years ago; and, if my memory serves me rightly, I believe patents were afterwards granted to Mr. Joel and also to a Mr. Tatham, the former for the use of cocoa-nut fibre separator, and to the latter for the use of sawdust and cellulose packings in combination with lead or other alloys for storage batteries, and as neither of these batteries have ever come to the front as a success, I presume the inventors came to the same conclusion as myself, that there was no value in the supposed inventions, or we should have heard more about them.

The use of a little permanganate of potash, carbonate of soda, sulphate of soda in combination with mercury,

if well mixed with the acid solutions, or even compounded with the lead when in a molten state (although not a new idea), has undoubtedly certain advantages—it assists formation, besides making the plates more homogeneous when used in combination with the Woodward, Planté, or other type of spongy lead plates.

As a matter of history, I may say that the use of carbonate of soda is a very old idea, and was recommended by me some years ago, and is duly recorded in the *English Mechanic* notices, and anyone interested in this subject can, by referring to same, find the report.

Moreover, I may mention that I supplied Mr. J. S. Sellon with specimens of this class of spongy lead compound type plate as far back as 1885; also Mr. Crompton in the year 1887—both of whom can testify to the fact, should Mr. Barber-Starkey require further verification of the fact—consequently further comment upon this point from me is unnecessary.

I may say that sawdust and all fibrous packings and separators have a tendency to absorb and retain moisture, and owing to their porosity will occlude gases, which is an advantage; but this method of packing the plates does not and will not prevent evaporation, as Mr. Starkey supposes, and the reason why he found his cells in such a placid state was simply because they had been kept idle and at rest, for it is well known by all experts that the evaporation of the liquid never occurs to any great extent, except in cases where the cells are either overcharged or have been too rapidly discharged when in use. Evaporation will then occur, which is caused by the expansion of the ethereal energy stored up in the shape of minute molecules consisting of “a something,” the component parts of which have yet to be determined by the aid of chemical science, which mysterious element may probably be a compound of etheralised ozone, or a species of azotic gas, most probably absorbed by the positive plate and held in combination with the oxide element contained in the cell. I have my own views upon the matter, but not being so well versed in chemical matters as I should like to be, I must leave the solution of this problem to our chemical *savants* to solve.

Arthur Shippey.

#### The Lineff Electric Traction System.

I read with considerable interest the careful and ably written report in your last issue by Mr. Kapp upon the new Lineff system of electric traction. The report itself is very fair and impartial—such as one might expect from the author—but I should certainly like to touch upon one or two points in this report, as well as the system described.

In the first place I feel pretty certain that, unless an absolutely rigid base support were given to the insulated rail sections, the inventor would speedily find them sinking down so much that they would be in contact at many points along the line with the internal conductor, and the galvanised iron strip would not be able to rise and make contact for the simple reason that it might be already wedged tightly between the conductor and the external rail, so making contact very effectually and permanently. Possibly I am doing the scheme an injustice from sheer ignorance, and when drawings appear this point may be shown to have had suitable attention. Nothing, however, will serve short of imbedding the insulated rail sections upon a good solid conduit, which also contains the conductor.

Even Mr. Kapp's apparently severe test of passing a heavy steam roller along the line does not altogether vouch for its efficiency; a single test like this does not compare practically with the ceaseless wear and tear of everyday traffic.

So long as a rigid connection is kept up between the conduit and insulated rail sections the device may be depended upon, but in proportion as this point is considered, so also are increased the difficulties of insulation.

Next, I must say that Mr. Kapp seems to have forgotten the old saying that refers to the weakest link of a chain; if any line has a minimum insulation resistance of 600 ohms and a maximum of 4,000, then the practical insulation resistance of that line ought, I think, to be looked upon as 600 ohms, and not as  $\frac{600 + 4,000}{2}$ .

An engineer is not altogether justified in reckoning on more than he can always and absolutely swear by; and as regards surface leakage, I fear this system (especially in our wet climate), would prove too wasteful for extended use.

Then, again, Mr. Kapp is, I think, a little unfair to the battery cars when speaking of the greatly increased weight to be carried.

From particulars of a large number of battery cars—all, indeed, that I could learn anything about—I found that the weight of the necessary cells complete was as nearly as possible that of the seated passengers at full load.

If the 20 passengers on the Lineff car weighed as much as the 3 or 4 tons that Mr. Kapp speaks of, then all I can say is, that they must have been in the prime of health and vigour—remarkably fine specimens, in short. A ton and a half of decently behaved cells ought to be ample for carrying 20 passengers along an average road.

One would wish very much for the sake of electric traction that one could see a prosperous future before such a system as that of Mr. Lineff: it is ingenious, it is novel (*pace* Mr. Holroyd Smith) and offers many advantages. But I fear the disadvantages would prove—in its present form—too serious to allow this method an extensive use. If practical service proves this feeling to be wrong, no one will be more pleased than

Frank B. Lea.

July 28th, 1890.

#### Secondary Batteries.

Referring to your article contained in your issue of the 25th inst. upon the merits of the Edinburgh paper upon “Storage Batteries,” it would appear that when speaking of the relative ampère-hours between the E.P.S. 7L cells and the ampère-hours obtained by Prof. Ayrton and his assistants, you lost sight of the fact that five instead of seven plates were used in the latter's cells.

Passing on to your reference to the “author's” concluding remarks, you think that further study and research into the chemical actions, &c., of the present storage batteries might be the means of increasing their efficiency.

I would, however, remark, for the benefit of those interested, that in my opinion any further labour in the direction of your suggestion would be time and capital lost, unless (after taking all the defects of the present batteries into consideration) improvements to the extent of 100 per cent. were obtained, which would be necessary to hold its own.

Progress.

July 29th, 1890.

[In the experiments at the Central Institution “7L glass cells” were used, containing *five* plates, but our clerical error does not in the least affect the sense of the article. We did not state that “further study and research into the chemical actions, &c., might be the means of increasing their efficiency,” but what we did say was that the promised “results on chemical investigations will be looked forward to with anxious interest by a large portion of the electrical fraternity,” and we maintained that the efficiencies obtained by Prof. Ayrton and his colleagues were, in our opinion, too high, and should not be relied upon in practice. Our correspondent must have had very sad experience with secondary batteries, and we cannot agree with his views as to an abandonment of all further research in this direction.—EDS. ELEC. REV.]

## PROCEEDINGS OF THE BOARD OF TRADE.

THE Board of Trade has issued a report respecting the applications for orders and proceedings of the Board during the past year. There were 161 applications of which 45 were made by local authorities and 116 by companies or individuals, 23 relating wholly or in part to the County of London. The report states that a modified form of provisional order was made necessary, before the model form settled last year for the metropolis could be made applicable to districts outside the Metropolitan area. In accordance with the Acts all orders granted to companies have been with the full consent of the local authority for the district. When applications have been made by a company and a local authority, the preference in accordance with the rules has been given to the application of the local authority. A clause, however, has been inserted in the orders and licences which enables the local authority, if it thinks fit, to transfer its powers to any given company, with the consent of the Board of Trade; 67 provisional orders have been granted, chiefly to electric light companies, but many have been refused on the ground of not receiving the consent of the local authority; 12 licences have been granted to private persons, companies and local authorities.

A question having arisen as to the interpretation to be placed upon the portion of the Schedule of the Electric Lighting Act, 1882, defining local authorities in Scotland, the Board of Trade consulted the Scotch office, who were of opinion that in certain cases in which authorities in Scotland were authorised to supply gas, they were not the local authority for electric lighting purposes in the capacity in which they supplied gas, and would not be able to utilise the gas rates for electric lighting purposes in the event of their obtaining powers to supply electrical energy.

In the appendix to the report, the regulations are given for the protection of the public safety, also for the protection of the electric lines and works of the Post-

master-General, but these are word for word the same as those published for the first time in the REVIEW for August 30th of last year, and which formed the subject of a leading article in the same issue.

## CAPITAL PUNISHMENT BY ELEC- TRICITY.

UNDER date New York, August 4th, a Dalziel telegram read :—"All America is greatly excited about the fate of the murderer, Kemmler, who, it is now believed, will be executed to-morrow night." Probably all America is now more than satisfied; for after many months of alternate hope and despair, the poor wretch has been done to death. Our readers do not need reminding of the various episodes in this terribly realistic drama, during a period which must have entailed upon the condemned man an amount of mental anguish such as no mortal ever before endured, neither need we dwell upon the combination of circumstances which led to the adoption of electrical execution in New York State as the means of capital punishment. All the incidents which have resulted in the first and, it may be, the last, despatch of criminals by this agency, have been chronicled in our pages.

For several days past the newspapers have published sensational paragraphs concerning the preparations for the prisoner's end. His own bearing at the thoughts of his approaching fate was said to be that of a maniac, the tests of the death machinery were reported in terms of the most absurd nature, and the manner in which the culprit was to spend his last moments has been discussed to the veriest detail in language calculated to shock the most hardened reveller in the horrible.

These incidents are as nothing, however, compared with the doubtlessly grossly exaggerated and sickening reports of the execution itself; reports which, from their improbable nature, must be taken with a grain of salt until official accounts of the death stroke reach our shores.

Nevertheless, there is enough of truth in these highly coloured statements to send a thrill of horror throughout the world. That a *thrice*-repeated application of the current was necessary before the spirit of the condemned man left its earthly tenement, we do not for one moment believe, and with the numerous cases of accidental deaths from high-tension currents before us, we can scarcely think it credible that a carefully-planned scheme to deliberately kill should entail a lengthened period of suffering, when a chance contact has so often resulted in what has, to all intents and purposes, been instantaneous death; indeed, we have hitherto tried our best to prevent fatalities from electricity, and yet many lives have been unwittingly sacrificed. Still, so far as can be gathered from the reporters, it would appear that both in preliminary trials and at the final scene the machinery did not come up to expectation, and so far as it is possible to judge from the garbled versions given by the newspapers, we imagine that the engine was insufficient for its purpose. However this may be, we have to acknowledge the fact that although Kemmler is no more, his execution has been at once a bungle technically, and socially and politically a mistake.

However much we may wish to believe that New York, from humane desires, made electric execution the legal method of expiating one's crimes, there is only too much reason to fear that it was introduced and promoted until it became law by those who had political and personal motives to serve; humanity was ostensibly the plea, but the real reason is less fathomable, although perhaps not altogether beyond one's depth.

Even in the telegrams from America, on the day of execution, it is easy to perceive these conflicting interests at work, and, if we are not mistaken, a certain section of the electrical industry is more or less involved.

As we have previously remarked, it is useless to comment upon the use or abuse of the electrical machinery until authentic details of its performance come to hand, but at the same time we feel that some sort of protest should be brought against the indiscriminate statements which have been scattered broadcast throughout the land. If, as one of the electricians who was present says, "everyone in the room lost his head," how much weight are we to attach to the ghastly descriptions of Kemmler's contortions and apparently agonising sufferings? For our own part, we do not give credence to the statements that the first application of the current was ineffective, although, as the reports of those who were present are so conflicting, we shall probably never learn the exact truth of the matter.

Without expressing any sympathy with the murderer, who seems to have been of that type of man for whom no fate is too bad, it would seem that, as he had for more than a year been the subject for bandying scientific and legal argument throughout the different courts as to whether death by electricity was or was not "cruel, unusual, and unconstitutional," it would have met the ends of justice if he had been kept to penal servitude for life. Whether the effect upon the American

populace will be of a demoralising nature remains to be seen. The *Standard* thinks so, and that it can hardly be over-estimated. On the other hand, if the new law stands, it may have a deterrent influence on crime, and, if this turns out to be the case, the first electrical execution may not have been carried out quite without some compensating benefit for the horrors which were attendant upon its enactment. But it cannot be denied that the whole affair partook too much of the nature of a show, and the conversation reported to have arisen between doctors, warder and criminal would seem laughable were it not that the fate of a human being was the subject of the melo-dramatic episode. Indeed, one can scarcely get rid of the feeling that in some respects we are simply reading a criticism of an execution scene in a new and thrilling stage play. The utter lack of solemnity throughout the whole of the proceedings, the numerous assemblage permitted to participate in the tragedy, and the clumsiness with which the fatal stroke seems to have been administered, all combine to make one ask whether all this theatrical display can really have been an incident of to-day. That such was the case is only too true, but let us, for humanity's sake, hope that a like scene will never again figure in the theatre of life.

In the REVIEW for June 4th, 1889, we carefully considered, from various standpoints, the question of execution by electricity, and notwithstanding the impression which the bungling over Kemmler must have produced in the public mind, we do not think there is any need to modify anything we then said. We confessed that at first we were reluctant to entertain the idea of electrical means being adopted for the purpose. But this was mere sentimentality—selfish sentimentality; and when we came to reason calmly, we could not perceive that we had more cause to object or complain than would the hydraulic engineer if death by drowning were proposed, or the cutlers of Sheffield, if the guillotine were to be brought into use in this country. The trend of civilisation, moreover, being towards lessening rather than increasing the horrors of capital punishment, it behoved us to consider whether death by electricity could not be made immediate and sure, for the rope has not been infallible. We thought so, and again we assert our belief that in proper hands there need be no hitch and no fear of failure with the electric current.

The *Standard* on  
Electrical Executions.

YESTERDAY's leading article in the *Standard* concludes as follows:—  
"The demoralising effect which such a scandalous scene as that enacted yesterday must have upon a large portion of the population of New York, and, indeed, of the United States, can hardly be over-estimated. The publication of minute accounts of every detail of what took place made the thrice-repeated efforts to stamp the life out of Kemmler visible to the whole nation, and fed the desire for sensationalism already too largely pandered to in the New World. The American public was yesterday thrilling with anxiety, not to hear that a brutal murderer had paid the penalty of his crimes, but to learn how long, and with what particular circumstances of horror, an alternating current is in destroying a human being.

The criminality of the man to be executed was not thought of. Kemmler was simply looked upon as a subject who might fairly be used for the great experiment. That the existence of this unwholesome and degrading sentiment shows any special depravity on the part of the New Yorkers we do not desire to assert for a moment. Electricity for the last few years has been the toy of the American people, and they have employed it for every conceivable purpose. At last some ingenious mechanist suggested that it should be used to get rid of criminals. The idea seems at once to have captivated the minds of the State Assembly, and they proceeded to adopt the suggestion. No doubt they soon grew persuaded that they were acting in the interests of humanity, though, in truth, they were lending themselves to a popular craze, and were merely endeavouring to show that there was no end to the wonders of electricity. Such levity, had it been conscious, could only have been described as inhuman; as it is, we must condemn the lack of judgment which prevented the members of the two Houses realising that they were prostituting the sacred work of legislation to the vilest sensationalism. Had the infliction of the death sentence by hanging outraged public opinion by constant failures, and had it thus become necessary to devise some new method, it might have been possible to find an excuse for the action of the Legislature. No such considerations, however, existed to influence them. The law, as already remarked, was simply and solely the outcome of an electrical craze. When this was the origin of the Act, it could have no other effect but that of demoralising the whole tone of the community in regard to capital punishment. Even had the process worked well instead of badly, it must have tended to make people look upon executions as sensational exhibitions of the powers of modern science. As it is, it is impossible to be sure that torture of the most excruciating kind has not been added to the death penalty in New York. But will popular feeling in the States allow the recent alterations in the law to stand? We doubt it. The Americans are, we believe, not less humane than their kinsfolk on this side of the Atlantic, and the sickening spectacle of yesterday will kindle a feeling of horror and disgust which neither Congressmen nor Senators will be able to disregard."

Electric v. Steam  
Traction for Elevated  
Railways.

THE *Financial News* published an article on the 25th ult., entitled "Electricity as a motive power." It was mainly based upon the experiments of Mr. Moss, of the Manhattan elevated railway of New York, and the results to the casual observer are calculated to lead him to the belief that electric traction is a fraud. It seems, however, that Mr. Moss must have got hold of some electrical plant belonging to a prehistoric age, as may be gathered from the following:—"Leaving Thirtieth Street, for instance, up a gradient of about 1 in 60, the horse-power exerted by the driving engine indicated 395, while at the same time but 7.6 horse-power, as indicated by a dynamometer, was being exerted to pull the train, showing less than 2 per cent. of the power of the engine transmitted to the train at that instant." We would like to know what kind of conductors were used for conveying the current and the state of their insulation, but on these points we find nothing. The *Financial News* is not improving the chances of com-

mercial men taking to electric traction by quoting figures which give one side of the matter only, but perhaps the policy of that journal lies in an opposite direction; in any case another paper, the *Railroad Gazette*, shows, from Mr. Moss's own figures, that propulsion by electricity, instead of being four times as expensive as steam traction for the elevated railway, shows a decided economy.

THUS runs the verdict of the jury which last Saturday met to consider the death of Private Sanford, who while watching a cricket match was killed by lightning, at the same time several companions also were severely injured. To say the least it is surprising that a body of men under the guidance of a coroner, who we presume to be an educated man, should return so anomalous a verdict. To appreciate a verdict of that character we must go back to the days when the ducking stool and the moot hall were time honoured institutions. Doubtless there would be many peculiar verdicts when the supernatural and mysterious influenced the mind, but one would have thought that we, in the 19th century, knew a little better. As showing the logical conclusions of the jury, the conduct of a Doctor Trask, who restored animation in the injured men, was highly praised, and owing to his exertions one man who would have died was restored. We are afraid that the worthy doctor must have defeated the ends of Providence by his timely act.

What Constitutes  
an Invention.

THE following extracts are from the opinions of three of the best American judges, and will probably suffice to define what constitutes a patentable invention, which is interesting to everybody:—

An invention, in the sense of the patent law, means the finding out, the contriving, the creating, of something which did not exist and was not known before, and which can be made useful and advantageous in the pursuits of life, or which can add to the enjoyment of mankind. In other words, the thing patented must be new; and it must be useful to an appreciable extent, though the measure of that usefulness is not material. Any degree of utility appreciable by a jury is sufficient, upon the question of utility, to sustain a patent. . . . . Invention is the work of the brain, and not of the hand. If the conception is practically complete, the artisan who gives it reflex and embodiment in a machine is no more the inventor than the tools with which he works. Both are instruments in the hands of him who sets them in motion and prescribes the work to be done. Mere mechanical skill can never rise to the sphere of invention. The latter involves higher thought, and brings into activity a higher faculty. Their domains are distinct. The line which separates them is sometimes difficult to trace; nevertheless, in the eye of the law, it subsists. The mechanic may greatly aid the inventor, but cannot usurp his place. . . . . The simplicity of an invention, so far as being an objection to it, may constitute its great excellence and value. Indeed, to produce a great result by very simple means, before unknown or unthought of, is not unfrequently the peculiar characteristic of the very highest class of minds. A subject matter to be patentable must require invention; but it is not necessarily the result of long and painful study, or embodied alone in complex mechanism. A single flash of thought may reveal to the mind of the inventor the new idea, and a frail and simple contrivance may embody it. Some inventions are the result of long and weary years of study and labour, pursued in the face of abortive experiments, baffled attempts, and finally reached after the severest struggles; while others are the fruit of a single happy thought.

## THE EDISON PHONOGRAPHIC TOY.

(A BANK HOLIDAY RHAPSODY.)

FROM the giant mind of the mighty Edison has sprung the crowning boon and blessing to men and infants. Monday last week saw the lists open for subscriptions to the Edison Phonographic Toy and Automaton Company, Limited, and Wednesday witnessed their close. In that time, if all went well, £300,000 of capital was paid in to Messrs. Brown, Jansen & Co., to the credit of the undertaking, of which £270,000 is to benefit the vendors and £30,000 the shareholders—perhaps? A military baronet holds the chair, with another soldier and three civilians as colleagues on the board, and there are five several firms of brokers to the company. Brokers live on commissions; commissions depend on transactions in shares, so it looks as if these were expected.

If you want to bore a man or boy try to instruct him; if you want his love, although temporarily, it may be, amuse him. For years we have done our best to instruct the public, and, accordingly, have not amassed a fortune. Oh! that we had earlier perceived the right path, become speaking dolls and sold ourselves for £270,000, less commission to brokers.

Perhaps the promoters would have done wisely to have rested their hopes ostensibly on the doll business, and not have referred in the prospectus to the utilitarian possibilities of the invention, unless they had proceeded further, and touched upon the more important uses which must infallibly follow. We are to have "talking automata in bar rooms, restaurants, cigar shops, and show-rooms of all kinds, to call the attention of customers to particular articles." Why stop at this dull, prosaic view, when the vista into which even our dull mental vision can penetrate is so glorious? With what rapture must the Wizard of Menlo Park have peered into the future of the talking doll after a few years of development. We can only suppose that his well-known modesty kept him from putting it all in the prospectus, or else the directors cut it out to save expense in printing and postage.

The uses enumerated in the above quotation seem ill-chosen. Surely Messrs. Spiers and Pond understand human nature better than to supplant their pleasant young ladies by talking automata? There is a sympathetic electric current induced in sexes of opposite signs by nature herself, and the most modish robes and a three guinea head of real hair hanging over the glass of bitter, and saying "tuppence please, thank you," would fall stale, flat, and unprofitable upon the ear of the dude. Again, "What is the next article?" is irritating enough to the average male, but spoken by an automaton, possibly with an American twang, would raise his evil passions to such a pitch, that the said figure would be in a parlous state, if not actually demolished by the umbrella of the irate one; in which case no enlightened jury would return a verdict other than justifiable dollicide.

But think of that poor man who, having lost his wife, never slept again because he missed the curtain lecture. Had he but possessed a phonographic image, into the "body" of which (price 12s.) the dear departed had once spoken the words of admonition, he could have laid it reverently on the pillow by his side, and let it off nightly at the appointed hour. The same old tale reiterated each bedtime would have been monotonous enough to send the most hardened insomniac soundly to sleep.

Not only will advertising media, but religion be extended. The poor district which cannot afford an incumbent could go to "between £3 and £4" for a phonographic automatic parson. The lights of the Abbey and St. Paul's, of the Tabernacle and the Temple, can have an illimitable sphere of action, and let us hope a handsome honorarium, at per annum or per hour, for preaching all day and every day at phonographic bodies, which can be despatched by parcels post through the length and breadth of the land, ensuring eloquence and sound doctrine, and setting free to take

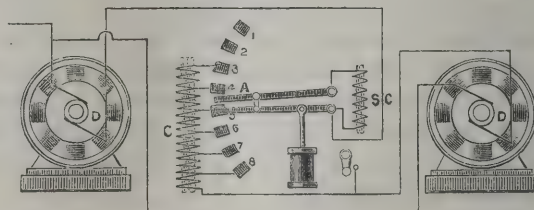

their place in the battle of commercial life, alike the high church curate and the young baptist minister, to the detriment of tennis, no doubt, but to the good of the community.

Fancy an age of phonographic *prima donnas* in every village schoolroom, and the more than ever automaton chairman reeling out well-considered speeches at annual meetings. Or say, Mr. Gladstone is indisposed in consequence of an adverse vote, would his verbosity be diminished? Not at all. Up stands his *alter ego*, and the exuberant phrases flow. An Irish member is sick; his double takes his place with the extra advantage that no calls to order would have any effect; no Speaker could stop him unless the bauble were for once made useful to literally knock his arguments to pieces.

That we do not spin this article out into many volumes is simply that our space is limited. It is a misfortune that scientific commercial companies always choose the days between the issuing of the technical papers for the bringing forward of their prospectuses, and we are debarred from helping them by our praises in time to aid their subscriptions. All we can utter is: "Too late, too late; you cannot enter now."

## METHOD OF SYNCHRONISING ALTERNATE CURRENT MACHINES.\*

IT has been the common practice to make the multiple connection of alternating current generators or motors after the impulses are observed to synchronise, various devices being used for determining the times of synchronism. In the method, which is the invention of E. W. Rice, jun., of Lynn, Mass., two or more alternate current dynamos or motors which are developing or running on circuits of approximately the same potential difference, may be coupled in multiple at any time without any special preliminary observation. In a few words, the invention consists in bringing the two machines

METHOD OF SYNCHRONISING ALTERNATE CURRENT MACHINES.

to synchronism by interposing a reactive coil in the armature circuit between the machines to be connected. In order that the operation of the method may be the more easily understood, it may be explained that the electrical activity displayed in this reactive coil depends upon the amount of current flowing through it. This amount in turn depends upon the difference in the phases of the currents passing to the coil. The effect of this action is to retard or accelerate one or the other of the machines until the phases of the impulses coalesce, because this is the condition of least resistance in the combined circuits. Referring to the diagram which illustrates the method, D is an alternating current dynamo, and D' is another and similar dynamo or motor. These are connected, as shown, with a variable reactive coil, C.

Switch arms, A, are insulated, one from the other, but are connected through a smaller reactive coil, S, C. These arms can be moved over the numbered contact plates. Assuming that the dynamo, D, is running, and

\* Western Electrician.

it is desired to divide its work with the machine, D', or in case it is desired to throw on the machine, D', as a motor, the method of procedure is as follows:—The arms, A, which, when the machine, D', is idle, are supposed to be resting on the contact pieces, 1 and 2—that is, open circuited—are moved, so that the lower arm connects with the contact piece, 3. In this position the working circuit of the machine, D', is closed with the circuit from the machine, D, through the reactive coil, C. This coil, with the lower arm in the position just mentioned, has all its wire in circuit, and is therefore developing its maximum counter electromotive force. Now, by moving the levers from contacts to contacts, a current from one machine or the other is permitted to act gradually so as to accelerate or retard the machines and bring the alternations into perfect synchronism before connection is made through the ordinary conductor of practically no resistance or reaction. If it is desired that one machine shall take a larger portion of the load than the other, the reactive coil, C, may be left in the circuit connecting the second machine. The function of the smaller reactive coil is to prevent sudden fluctuations of the current when the arms are moved over the contacts.

### THE INTERNATIONAL EXHIBITION OF MINING AND METALLURGY.

LAST year a suggestion was brought forward that an exhibition should be held in London this summer for the purpose of demonstrating the great advances which have of late years taken place in mining and metallurgical practice. The idea, which was favourably received in different quarters, has culminated in the present exhibition which was opened at the Crystal Palace, on Monday last week, by Lord Thurlow. The exhibits are distributed throughout the galleries and the palace building, whilst the machinery in motion is erected in a special building built at the north end of the palace. Most of the Colonial Governments are officially represented, that of New South Wales, which occupies the south nave and a large portion of the galleries, having the largest and most interesting collection of different minerals. Many English and foreign mining companies show a number of mining and metallurgical exhibits.

It was expected that several important electrical firms would be *en evidence*, but only a few are represented. The Planet Electrical Engineering Company has a small installation for lighting the machinery hall. The plant comprises a Crompton continuous current dynamo, driven by belting from a Rigg rotary engine. The machinery hall is lighted by 20 Planet arc lamps of 6 ampères, the lamps being arranged two in parallel. Mr. Lars Bristöl shows several of his miners' lamps having accumulator cells. The main feature of these is the fact that the glow lamp is covered by an external thick glass dome which, if accidentally broken, throws the lamp off its holder and interrupts the circuit. It is claimed that by this means the possibility of any explosive gases being ignited is entirely removed. Messrs. J. Davis & Son, of All Saints' Works, Derby, exhibit, among other articles, protector fittings for incandescent lamps, ceiling roses, ammeters, voltmeters, switches, electric blasting apparatus, &c. Various electric firing batteries, galvanometers, electric wires and electric mining appliances are to be found on the stand of the Cotton Powder Company, Limited, and similar apparatus are also on view by Nobel's Explosives Company, Limited. Messrs. Woodhouse and Rawson United, Limited, have an interesting collection of electric bells, batteries, lamps, &c.

Of engineering firms, Messrs. Davey, Paxman & Co. have the largest display. They show, among others, a 40 H.P. horizontal engine and two horizontal boilers of

40 H.P. This engine drives a line of countershafting from which the machinery in motion is mainly operated. There are also on view an 8 H.P. compound portable engine, an 8 H.P. single cylinder portable engine, a 6 H.P. girder engine, an "Essex" boiler, &c. Messrs. Dick, Kerr and Co. exhibit a Griffin gas engine. The only glass case in the Machinery Hall contains a display of some useful goods manufactured by Messrs. W. H. Willcox & Co., including their special make of wire-bound hose, such as is used for the delivery of petroleum from ships and by the Fire Brigade. Leather belting is shown in various forms, as well as a number of other articles in daily use in mining operations.

The exhibition will remain open until the middle of October.

### SOME DEFECTS IN PHYSICAL TERMINOLOGY.

By PROF. A. E. DOLBEAR.

WE abstract the following from the New York *Electrical Engineer*:—In the subject of electricity the lack of definitions in the terminology has led to a great deal of confused thought, but our actual knowledge of the character of electricity is much greater than many suppose it to be. Maxwell and others have asserted that whatever it may be it is not energy, while others, as represented by Preece in his late presidential address, assert that it is energy. Curiously enough Maxwell declares that it cannot be energy because electric energy is a *product* of electricity, E, into a current, C.

Eidlund and some others have thought electricity to be identical with the ether, while still others have imagined it to be a fluid, or two fluids, or some kind of matter with the fundamental property of matter—namely, *mass*, left out. It is not very difficult now to see how such varied conceptions arose. An electrified body affects the space about it, or, as we now say, it produces an electric field which is known to be a stress in the ether, and that implies a strain in the electrified body. It is also known that such stress is propagated in the ether with the common speed of ether waves—namely, 186,300 miles per second. The speed of this movement has been measured by so many, and in so many ways, that there is no doubt about it, and since the experiments of Hertz there is no room for doubt as to the existence of the ether.

What we now know is that states of stress in the ether are propagated at a definite rate in it, which rate depends not upon the source of the movement but upon the property of the ether to transmit movement; so, whether heat movements or electrical movements are antecedent makes no difference. We find no difference in perceiving the relation between the vibratory molecular motions and the resulting waves in the ether, but here is a precisely analogous case of electrified molecules and the ether propagating a motion, which implies, if anything, that molecular motion is the source of the ether displacements. One person will give chief attention to what is going on in the electrified matter, and another person to what is going on in the ether, and they come to different conclusions as to the nature of electricity, while a third person who notes their discrepant notions concludes that no one knows anything about it. What we call electricity originates in matter, and there is no evidence whatever that it ever originates apart from it. As Rowland has somewhere said: "It begins in matter and ends in matter." The conditions for its origination are differing and interfering molecular motions, whether in a thermopile, a galvanic battery or a dynamo; the conditions for its transference are a continuous material conductor, for it cannot traverse a vacuum. The effect upon the ether

we call an inductive effect; and just as in heat phenomena we have a transference and a transformation, so is there also in electrical, both a transference and a transformation. In heat phenomena, where matter is placed in the *thermal field* so that the ether undulations fall upon it, the matter is heated. Likewise, when matter is placed in an electric field the matter is electrified. The cases are exactly analogous, and one is therefore justified in making the terminology appropriate to the phenomena; and whenever there has been a transformation in the motion, another name ought to be adopted and not let the old one do double duty. If molecular motions of any kind be called electricity, then it is not proper to call any effects in the ether by that name. If the effects we study in the ether be called electricity, then do we need a name for what takes place in matter, for one is the effect of the other.

If one adopts the doctrine of the conservation of energy, and also that the matter of the earth is practically a constant quantity, it will lead him to conclude that all the varieties of energy are due to the various forms of motion that matter may have. If, also, one perceives that motion of any kind, at any place, implies antecedent motion, he will not feel the necessity for looking for hyperphysical explanations for any physical phenomena. For instance, when one sees the light and feels the heat from an electric arc lamp, knowing the nature of both the light and heat as being but particular forms of motion—one in matter, the other in the ether—he could logically look for nothing but some kind of motion that had been transformed to produce such effects. It is entirely immaterial what the character of the motions may be that produce electrical effects—that may remain to be determined by experiment—just as in the case of heat after the work of Sir Humphrey Davy and Count Rumford, it was then settled what the *nature* of heat was—namely, a molecular motion of some sort and not an entity. It is only within a few years that the character of the motion has been determined. In like manner we may say that we know what the *nature* of electricity is—that it is also molecular motion of some sort to be experimentally determined.

There are numerous reasons for thinking it to be a rotation as distinguished from a vibration. One of the chief of these comes from a study of electro-magnetic effects in the ether. It is generally agreed that this magnetic effect in the ether is of the nature of a whirl, or rotation, and in numerous treatises these whirls are pictured, but I do not remember to have noted that anyone has pointed out that a whirl in the ether implies a rotation of a molecule, for a simple reason that an undulation in the ether implies a vibration of the molecule. To me this appears to be necessary, but whether the motion be that or some more complex kind does not so much matter—it will be discovered in time.

There is one more important matter I want to allude to, and that is the expression first used by Maxwell, namely, "Light as an electro-magnetic phenomenon." Waiving for the time the criticism that light, being a physiological phenomenon, is therefore entirely inappropriate here, there still remains this fact that the ether waves from heated bodies move in straight lines, and unless deflected by the reflections and refractions of matter, will continue indefinitely on in the same straight line, making the *field of a heated body* as extensive as the universe; while the field of an electrified body depends upon the proximity of masses of matter, and practically is always limited in extent, and the observed lines are always curved. So if the two kinds of waves were really parts of the same movement, what is called a ray of light would seldom or never be found to move in a straight line for any considerable distance. If, on the other hand, the wave that originates in a vibration continues in a straight line only so long as it moves in homogeneous ether, and has its place of vibration changed by passing through a space of ether that has been electrically warped, as we experimentally discover to be the case, it would seem to follow that the two kinds of motion

in the ether are fundamentally unlike. Either can exist without the other, and therefore they ought not to be called by the same name.

## EDINBURGH EXHIBITION.

(Continued from page 126.)

No. 162.—*The Electric Engineering Corporation, Limited.*—This exhibit includes a Statter-Brunton constant current dynamo as supplied for driving the tramways in the Via Flaminia at Rome. This machine is fitted with Statter and Brunton's patent automatic regulator and maintains a constant current of 30 amperes with a maximum E.M.F. of 750 volts at 750 revolutions. The machine is shown at Edinburgh driving three motors in series. These motors are placed on the stand. One of them drives a D.D. compound wound dynamo having an E.M.F. of 60 volts and a maximum current of 75 amperes at 1,300 revolutions. This machine is used to light the stand. Another of the motors is run light. They are fitted with constant current regulators which maintain an absolutely constant speed from full load to no load. A third motor is combined with a hoist and illustrates the adaptability of the constant current system for transmission of power for such purposes. The hoist may be started, stopped and regulated with extreme nicety. The system is fully protected by patent. The exhibit also includes a high speed engine with automatic governor acting directly upon the cut-out. This engine has single cylinders, since the available boiler space at the exhibition is low. An Atkinson 2 H.P. nominal gas engine is shown combined with a D.C. dynamo. This is used to drive arc lights in parallel the lamps employed being the Statter patent arc lamp.

The Corporation also exhibits a 20 inch projector fitted with patent diverging gear. The projector is made in brass and gun metal and complies with Admiralty specification. For the Executive Council it has equipped the electrical tramway running from the Caledonian Station to the Exhibition. Each car is driven by a 15 H.P. motor, the driving power being derived from two 30 unit Statter dynamos.

The trolley line exhibited by this corporation at the exhibition is  $\frac{1}{4}$  mile in length and travels over undulating ground, the highest point being 30 feet from the ground, and the lowest 15 feet. There are two trains, each consisting of a locomotive and four cars. The speed maintained is 5 to 6 miles an hour and the trains are prevented from any possibility of collision by the employment of a dead section in the conductor. The current is derived from the D.M. dynamo exhibited at the stand.

## HIGH VERSUS LOW-TENSION.

THE report of the Electricity Committee for the St. Pancras electric lighting, to which we briefly referred in our last issue, is, in several respects, instructive reading, and from the fact that the recommendations contained therein emanate from so high an authority as Dr. Hopkinson, it is of considerable value. But although there is every reason to regard the report as being founded upon a sound basis, it cannot be unreservedly accepted, in the absence of information showing how the recommendations are arrived at. Dr. Hopkinson, in reporting upon the schemes proposed by Prof. Robinson and Mr. Gordon, the one being for a continuous current 200-volt system, using three wires, and the other (that of Mr. Gordon) a 1,000-volt alternating system, states:—"If the distance to which the bulk of the supply is to be transmitted is about one mile, the two systems are about equal in cost; if it exceed a mile the alternating current at 1,000 volts is

cheaper than the continuous current at 200 volts, for less distances the continuous current is cheaper." As in the case of St. Pancras, the bulk of the work lies at much less distance than a mile from the station, the 200 volts system is recommended as being the more economical. There is, we think, a fairly general consensus of opinion as to the commercial advantage of a low-tension system for short distances, and therefore, as we stated, we may accept the recommendation as being sound. Still more interesting would it have been, however, if we could have had Mr. Gordon's explanations for his advocacy of a high-tension alternating transformer system, a system in which accumulators cannot be used, and in which the transmission of motive power is practically (at present, at least), impracticable. This latter point—the transmission of power—may not, however, be one of any great importance, unless it can be shown that there is, or is likely to be, any large demand in the district for the supply of motive force.

The reference in the report to Major Cardew's opinions on the advantages and disadvantages of the high-pressure transformer system, as used by the Chelsea Company, do not appear to be of any material value, as these opinions really do not compare the advantages and disadvantages of the high and low-pressure systems, they simply state what the high-pressure system will do, and not what the low-pressure system will not do; much of what is said applies equally to the two systems, as, for example, when it is stated that "It is also a simple system to work, and the dynamos are simple, and can be made in easily replaceable parts."

Messrs. Latimer Clark, Muirhead & Co. express the opinion—"we are certain that low-pressure continuous current system will be found the most economical, satisfactory, and enduring"—and they adduce certain reasons for their belief; these, however, are, we think, no reasons at all; they say that certain good results have been obtained from the low-pressure system, and give figures in support of their assertion, but with reference to the high pressure they say *we are not aware* that any alternating, high-pressure, or transformer system, could show anything like the same economy; "if they cannot prove that the high-pressure system is not economical they cannot be competent to express an opinion on the relative merits of the two."

From the point of view of cost only the low-tension system, as recommended against Mr. Gordon's scheme, shows a considerable difference, a difference which the report states "placed the scheme (Mr. Gordon's) quite outside the favourable consideration of your committee."

### RENARD'S VOLTAIC CELL.

THIS cell, the invention of Commandant Renard, will, it is claimed, give a considerable amount of energy in a very short space of time, or it will yield the same total amount of energy, gradually decreasing, with a duration of discharge proportionately increasing. The arrangement is of the bichromate of potash type, and its novelty consists in:

(a) The substitution of hydrochloric acid for some of the sulphuric acid.

(b) The suppression of the alkaline base, the bichromate being replaced by chromic acid.

Each cell consists of an elongated tube made either of glass or ebonite. The positive electrode is furnished by a very fine platinised silver tube (a carbon electrode is found to be unsuitable), and the negative electrode is a thin rod or wire of zinc.

The liquid used in this cell is composed of a mixture of two liquids, A and B, each of which is itself a mixture.

(A) consists of chromic acid and water, 0.530 of acid to 0.770 litre of water.

(B) consists of a mixture, in variable proportions, of hydrochloric acid and sulphuric acid.

If commercial hydrochloric acid be employed, it must be brought to a certain strength (18° Beaumé) by the addition of a little water. The requisite strength of sulphuric acid is obtained by mixing 0.450 kg. of acid at 66° with 0.800 litre of water, and the result should show 290° Beaumé.

The symbol, B, may be conveniently used in order to indicate the strength of the liquid, B, in percentage of sulphuric acid, thus B<sub>20</sub> indicates that the liquid contains 20 per cent. of the acid.

It is stated that the total electric capacity of the cell does not vary or behave in any erratic way, and that many experiments show that the available energy per second is practically quintuple of that which can be obtained with the same apparatus charged with the bichromate of potash and sulphuric acid liquid of the ordinary bichromate battery.

The following are figures given by Renard in support of these contentions:—

Strength of the liquid.			Maximum current.
Mixture of liquid A with	B <sub>0</sub>	.....	8.50 ampères.
"	"	B <sub>20</sub>	7.40 "
"	"	B <sub>40</sub>	6.80 "
"	"	B <sub>60</sub>	5.20 "
"	"	B <sub>80</sub>	3.50 "

Instead of sulphuric acid, sulphate of soda may be employed in liquid B, but the effect of the use of this salt is to reduce the total available energy per litre of liquid.

The best proportion in which to employ the constituents of the liquid is shown by the following table:—

No. of expt.	Joules obtained.			Composition of liquid.
	In the expt.	Per litre of liquid.	Per kilo. of liquid.	
1	44,900	200,000	170,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 40 gr.
2	48,000	215,000	176,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 60 gr.
3	52,200	233,000	185,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 80 gr.
4	56,900	253,000	197,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 100 gr.
5	56,000	250,000	184,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 150 gr.
6	46,100	205,000	144,000	{ HCl at 11° ... 200 cc. CrO <sub>3</sub> ..... 200 gr.

The liquid employed in No. 4 experiment should be the best for general use, for it gives 253,000 joules per litre. This liquid, however, has the inconvenience of being a little viscous, and of sticking to the surface of the zinc—effects which conspire together to produce a diminution of energy which is quite appreciable. In actual practice the liquid which is found to be most suitable is that used in experiment No. 2.

It is unnecessary to amalgamate the thin zinc rod or wire which forms the negative electrode. By reducing the diameter of this electrode, the density of the electricity at its surface is increased, and at the same time the consumption of the metal per second and per unit of surface is reduced.

The great activity of these cells necessitates the provision of a considerable cooling surface, for there is a large amount of heat generated; this fact has determined the adoption of the tubular form of cell.

**Electric Light at Fareham.**—The introduction of the electric light into Fareham is likely to be attended with some difficulties. A memorial signed by 50 inhabitants was presented to the Local Board on Friday last against the erection of electric lighting poles, on the ground that they would disfigure the town. It appearing, however, that an action at law was already pending in reference to the matter, the Board decided to await the issue of events.

## THE KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING STATIONS.

THE district over which the Kensington and Knightsbridge Electric Lighting Company has the right to supply electrical energy extends from Kensington High Street on the west to Albert Gate on the east, and from Hyde Park and Kensington Gardens on the north to the line of the Metropolitan Railway on the south. The original supply station erected by the company at Kensington Court commenced work in 1887, and has been continuously in operation since that time. It has been fitted with machinery capable of supplying between 20,000 and 30,000 lamps, and a second station at Chapel Place, Knightsbridge, has been constructed, which is able to supply another 20,000. The mains of the company have been laid in most of the principal streets of the district, and exceed 10 miles in length; they are all underground, and consist of concrete culverts made in the footways, having openings with removable covers opposite every second house. The conductors are bare copper strips resting on insulators, and the engineers claim that all future necessity for disturbing the surface has thus been avoided.

The system employed is the low pressure continuous current, assisted by accumulators to form a reserve of power and as a means of keeping the supply of current absolutely constant, and avoiding the chances of a breakdown. During the three years and a half the company has been in existence only one failure of the light has taken place, which occurred soon after starting. The working of this station, it is believed, is more economical than any other central station either in England or abroad; but, unfortunately, not being furnished with exact figures or data, we are not in a position to verify this statement.

The customers have paid for their electricity by meter record, and they appear to have been satisfied with the system of measurement.

The following particulars were issued by the company, and show the present condition of their system:—

Number of lamps ...	...	...	...	15,130
"    houses ...	...	...	...	178
Mains laid in miles	...	...	...	10½
Horse-power	...	...	...	750

The amount of power can be easily increased to 2,000 H.P., sufficient to supply a total output of 100,000 lamps, which is considered to be the full amount required for the district.

On entering the station at Kensington Court while the plant is running, it cannot but be favourably noticed that the moving machinery is working in comparative quietude, and that the absence of noise and clatter is in marked contrast to the din prevailing at several other stations we have seen. The engines being coupled direct on to the dynamos, there is a corresponding gain in compactness and economy of floor space over machinery driven by long ropes or belts.

The buildings comprise a main shed, whose floor is some feet below the level of the street, in which are erected the boilers, engines, and electrical apparatus, accumulator galleries on an upper floor, as well as on the ground floor, together with sundry store-rooms and offices.

There is ample floor space for a further and large extension of plant, should the requirements of future demands necessitate providing for an increased supply. The company, however, considers that the present equipment will suffice for the coming winter, and that unless an unexpected demand arises to strain the limits of the effective output of the machinery, no heavy alterations to this station will be requisite for some time to come, nor to the other station in Chapel Place.

Each engine and dynamo is fixed to a common bed-plate. The engines are of the Willan's type, and are provided with fly-wheels to ensure greater steadiness in driving the dynamos, which, as before mentioned, are coupled direct. The Kensington Court station is equipped with four engines of 200 H.P., driving the same number of large Crompton dynamos, furnishing

currents at 200 volts pressure, suitable for the three-wire system (on which principle the whole of the circuits will eventually be worked), and also three smaller engines of 80 H.P., each driving a single magnet upright Crompton dynamo. The steam power is developed by three sets of boilers of 250 H.P. capacity, constructed by the Babcock and Wilcox Company.

Massive leads are taken from the dynamos to switchboards erected in a small gallery specially set apart for the purpose, and by means of these every manipulation connected with charging, coupling, and other regulation of the currents is performed. The entire board has been designed in a thoroughly workmanlike manner, the mechanical engineer showing himself as prominent in the construction of the details as the electrician does in those points where his special knowledge is necessary. Instance the switch used for adjusting the number of accumulator cells for general regulation—the lever employed for working this switch has much of the character of those that are fixed in the signal boxes on railways for controlling the signals and points, and is of sufficient strength to withstand any wear and tear or rough usage that it will be likely to meet with. The electrical contacts present large surfaces, and much care and forethought has been exercised in ensuring good contacts between the parts when they are intended to operate.

In order to prevent, as far as possible, the loss between the terminals of the secondary batteries, the copper leads to the switchboard have a heavy section in the form of an H girder, which gives a very rigid conductor of ship-shape appearance.

There are several sets of accumulators, and of these two are placed in a stable at some distance from the charging station to assist in maintaining an even potential throughout the mains. A set is an aggregation of 56 separate cells of the Howell type arranged in series. Each cell of the battery contains 61 plates, and their dimensions are 8½ inches square by ¼ of an inch in thickness. The receptacle in which these 61 plates are placed is of lead with burned joints, and considerable attention has been paid to secure good insulation for the battery; each cell stands upon a plank painted with acid-proof pigment, and this is again insulated from the main frame by glass insulators. All timber in the supporting frame is painted with the above acid-proof application; while, not to neglect any means for preventing leakage, the contractors have paved the floor of the accumulator room with a special compound of bitumen and slate dust, a composition not only acid-proof but possessing good insulating qualities.

The normal output of the accumulators, or what may be better called the average discharge per hour, is 250 amperes, and the maximum allowed under contracts which must not be exceeded is 500 amperes. It would only be on an emergency that they would be discharged at the latter rate.

Aron meters are in use for measuring the current supplied from the stations, and the officials employed there speak very highly of their accurate performance in registering the precise amount of current consumed within a limit of error, so it is said, of less than a half per cent.

The Crompton system of underground mains, in use throughout the district, has been in successful operation for some years. The conductors are bare copper, supported on glass insulators in concrete culverts, under the footways. The conductors are composed of copper strip, one inch wide by a quarter of an inch thick; in some cases two or more strips are superimposed, supported at intervals in the culverts on glass insulators, which are arranged in sets, each set placed under a surface box having a removable cover, so that the insulators can be examined or replaced, or connections made to adjoining houses without disturbing the surface of the footway or roadway. These copper strips are strained tight, and held up by arrangements which can only be properly described and shown with the help of drawings. Such straining or fixing apparatus must be employed on straight runs, at certain intervals, depend-

ing on the weight of the conductors, and at points where the conductors deviate considerably from the straight line.

As the company, represented by the secretary and the contractors and their assistants, have been unsparing in their pains to render the installation of the electric light in their district as big a success as possible, it is to be hoped that the public, who occupy the houses along the route of the company's mains, will avail themselves to a large extent of the facilities thrown in their way, and use the electric current in such quantity as will suffice to somewhat recoup the Kensington and Knightsbridge Company for the heavy outlay to which it has been put in starting its system.

## ELECTRIC TRACTION AT SALZBURG.

[FROM A CORRESPONDENT.]

A VERY interesting electrical tram line for the conveyance of passengers will be opened in a few days at Salzburg for public traffic.

To an almost perpendicular declivity of the Rönchberg there is affixed a cable line, worked by electricity, with an exactly vertical track of the cars. The considerable height of the installation (75 metres) and the extensive arrangement for the electric working, secure for the undertaking a significance, though in its nature and outward form the name "passenger conveyance," in the sense of the lifts at hotels, would be most suitable.

As far as the shore of the Salzach the spectator perceives the slender iron framework of the line, with a double track for an ascending and a descending seat. The lower station contains, in addition to the entrance and departure platforms, the battery chamber, containing 126 accumulators of large make, supplied by the Swiss Oerlikon firm, and which supply the electrical energy required for the ascent. The electricity for charging the accumulators is supplied by the dynamos of the Salzburg electrical works, which have been in operation for some years. For this purpose a special cable lead has been laid down, so that the accumulators can be charged during the daytime, when the dynamos are not required for the supply of light. It is therefore hoped that this installation will considerably increase the remunerative character of the works.

At the upper station is the electromotor which acts by a simple transfer to rollers placed in juxtaposition, over which runs the bearing rope of the travelling seats.

The entire installation has been executed by the firm Siemens & Halske, who constructed the Salzburg electrical works and then handed them over to a limited liability company. The height of the lift, as already signified, is 75 metres, the weight of a travelling seat is 1,200 kilos. Each seat can accommodate 12 passengers, who in a few moments can be raised to the summit of the Rönchberg.

The fare proposed is 20 kreuzers each person for the ascent and 10 for the descent, which, with regard to the small distance traversed, cannot be regarded as very moderate. A restaurant and an extensive park are projected on the level of the upper station.

**Tenders for Lighting Sofia.**—The Foreign office has issued the following notice, dated August 2nd:—"With reference to the notice published in the middle of last May respecting tenders for lighting the town of Sofia by electricity, a despatch has been received at the Foreign Office from her Majesty's Agent and Consul-General in that city, stating that the adjudication will take place in the course of the next six weeks, and that any British firms desirous of competing should lose no time in communicating with Monsieur D. A. Zenow, of Sofia, or directly with the Mayor of that city, Monsieur D. Petkoff."

## REVIEWS.

*The Electrical Engineer's Pocket-Book.* By H. R. Kempe, M.I.E.E., A.M.I.C.E. 1890. Crosby, Lockwood and Son, London.

The aim and object of this handy book of reference cannot be better explained than by quoting the author's own words. "In compiling this book my aim has been to produce a book which should, as far as possible, truly accord with its title, viz., a pocket-book of useful "modern rules, formulæ, tables and data"—the matter selected being such as is required for daily use in practical electrical engineering and its various applications to the industries of the present day. So multifarious are the data required, that every person engaged in the practice of electrical engineering must have experienced the want of such a manual."

The information which the author gives has been (he remarks) "carefully condensed, and only that which, in the practical experience of myself, and of others with whom I have been associated, has been proved to be of constant value, has been included." The book extends to about 250 pages, and includes numerous illustrations. It is divided into twenty-one sections, as follows:—(1) Weights and measures; (2) Units; (3) Temperatures; (4) Electro-Chemistry, Primary Batteries, and Accumulators; (5) Electro-Metallurgy; (6) Current; (7) Resistance; (8) Capacity; (9) Galvanometers; (10) Fault Testing; (11) Wire; (12) Insulated Wire; (13) Electric Light Leads; (14) Electric Light, Dynamos, and Motors; (15) Rules and Regulations; (16) Telegraph Apparatus; (17) Telephones; (18) Miscellaneous; (19) Mathematical Tables; (20) Foreign Money; (21) Dictionary of Technical Terms.

It immediately strikes one with surprise that in the above subdivisions of practical electrical engineering, no mention whatever is made of submarine telegraphy. The omission is evidently intentional, as, beyond one mention in the index, "Cable cores, size of," this important subdivision of electrical engineering is apparently entirely omitted, save that, in "Miscellaneous," is found a diagram and note for "sheathing wires for cables," otherwise "submarine," does not appear in the index. Of course, there are formulæ and descriptions of "fault-testing," but as these are applicable to ordinary insulated electric wires, they cannot be credited to submarine work exclusively.

Under "Temperature" will be found—an arrangement very handy for reference—formulæ for the effect of temperature in the electrical resistance of various objects, such as copper, German silver, platinum silver, platinoid, gutta-percha, and India-rubber. The latter is given, it is believed, for the first time in any book, the writer not being aware of this useful information having been previously published. Although manufacturers are aware of the behaviour of India-rubber under the influence of temperature, yet this information has been invariably kept to themselves; the subject, generally speaking, being a sealed one. Is it because so little is known about it? At page 20 will be found a table of great value on this point: "Dividing coefficients for correcting the observed resistance of India-rubber at any temperature to 75° Fahr." Comparing this with a similar table for gutta-percha, it will be found that whereas G.P. alters from 1.00 at 75° to 1.982 at 66°, India-rubber only varies from 1.000 to 1.244 at 66.5°; a very marked difference in the influence of temperature on the two insulating substances. The author, in referring to India-rubber, is presumably understood to refer to "pure" rubber only, as *vulcanised* rubber is nowhere referred to. This is somewhat remarkable, considering the various qualities of this material, and the prominent position it now occupies as an insulator for electric light cables.

Under the heading of "Capacity" will be found formulæ for finding the inductive capacity of wires insulated with gutta-percha; and it is added, "for India-rubber the values are about 10 to 15 per cent. less," but as to the capacities of other material no mention will be found.

Nor is any allusion made to cables insulated with paraffin or other substances whose inductive capacity is considerably less than that of gutta-percha. As these forms of cables are very largely used abroad and also at home, especially for telephonic purposes, it is a matter of regret to find no mention made of them. But there appears to be an entire omission of any form of telephonic cable, whether underground or aerial, even the four-wire post-office form, and the over-ground "twist" seem to have been omitted. Under the same head of "Capacity" will be found a very useful and valuable "Loss of Charge" table showing approximate percentage of charge lost in a cable after 20 seconds' charge and one minute's insulation, corresponding to various values of F.R. ("capacity per knot  $\times$  insulation per knot"). The test for percentage of loss is an exceedingly valuable one, and with an ordinary electrometer the condition of an insulated wire can be immediately judged without the necessity of calculation. Too little value has hitherto been placed upon this form of testing, and where definite results are required without the mathematical values, then the "loss of charge" test is the quickest and best of those known.

Under the heading of "Electrification," page 59, there are some remarks of so valuable and so perfectly reliable a character that a reproduction is desirable, as the particular attention of those engaged in correct testing should be drawn to it.

"The galvanometer deflection in the insulation test should be perfectly steady; unsteady reading, provided connections are well screwed up and battery is in good condition and well insulated, means a faulty cable. The deflection will gradually decrease whilst the battery is kept on, the decrease (called *electrification*) being rapid at first and then gradually slower. The decrease will be quicker at a low than at a high temperature. It is greater with India-rubber than with gutta-percha." "It is of very great importance to have both ends of the cable core well trimmed, and quite dry when testing. The trimmed ends should be dipped in melted paraffin wax." To those engaged in testing and wishing to obtain reliable results, better instructions cannot be recommended.

In the section given to "Wire" will be found a large amount of very useful information, commencing with the "standard wire gauge," to which a note is appended. "This gauge is the only legal standard wire gauge for the United Kingdom." It is, however, not the only one in use, for the B.W.G. is still very largely employed. A comparative table of wire gauges—that is, the S.W.G., the B.W.G., and the American B. and S., is very handy; but the B.W.G. can be found on referring to "Glover's" useful tables, of which a large abstract has been made.

The section on "Insulated Wire" concludes with the following "general observations": "Too much care cannot be taken in making joints; a defective joint, although it may not for a time so far lower the insulation as to cause a serious leakage of current, is almost certain to go completely bad sooner or later. Similarly, an insulated wire which has an insulation resistance of several megohms (an insulation which is amply sufficient for working purposes, provided it remains constant), would be almost certain to fail sooner or later, if its normal insulation were several hundred megohms."

In the section "Electric Light Leads," the Board of Trade limit is given at 2,000 ampères per square inch of section, but calculations are usually made upon the 1,000-ampère limit; this is apparent in some tables given further on. It is pleasing to find that reference is frequently made to the work done by the late Robert Sabine, for in electric lighting several of his tables are to be found. The instructions given by him for the mechanical tests (see p. 131) for insulated electric light wires are worthy of consideration; but Sabine was one of those who worked before their time.

There are several other points to which attention might be drawn, notably, to a large amount of very useful information included in the "Miscellaneous" section, but space hardly permits of much further

reference. However, the tables at the end of the work will be found most useful and valuable, and tend to render the book very handy and complete.

The index is of an excellent character, and much time and labour must have been spent in rendering this as complete and correct as possible. So far as examination goes, it is about as good an index as can be met with. The work concludes with "a concise dictionary of electrical and technical terms in general use," which will be found of advantage to the many who have not been electrically brought up. As a very useful and handy help to those engaged in the various electrical industries, this work is strongly commended, and the author may fairly be congratulated on the successful carrying out the aims professed in his preface.

G. E. P.

#### *Galvanic Batteries, Accumulators and Thermo-Batteries.*

*A Description of the Hydro and Thermo-Electric Sources of Currents with especial reference to practical requirements.* By W. PH. HANCK. (Die Galvanischen Batterien, Accumulatoren und Thermo-säulen Eine Beschreibung der hydro und thermo elektrischen Strom Quellen mit besondern Rücksicht auf die Bedürfnisse der Praxis). Third edition. Vienna, Pest, Leipzig: Hartleben.

This work forms a volume of the "Electro-technical Library," issued by the publishers. The author, indeed, says in his preface, perhaps too modestly, that batteries must now seem to the electro-technician merely the out-grown "diseases of the childhood of applied electricity." The substitution of the dynamo for the battery has been indeed a revolution. It has taken electrical research out of the hands of chemists and handed it over to mechanics, and probably all the results of the change have not been favourable to scientific progress. Herr Hanck mentions that many a promising improvement has disappeared from the scene or has sunk into a subordinate position, and that his readers will have become suspicious of inventions which have come across the Atlantic or the Channel, and cautious concerning French discoveries, though guaranteed by the names of celebrities. In the present addition, in place of dazzling novelties, the author has inserted merely matter which has stood the test of experience.

Accumulators naturally occupy a considerable space. As regards thermo batteries, the missing link has not yet been found which should connect the furnace at once with the battery without the costly intervention of the steam engine and the dynamo or their equivalents.

*The Electric Light and the Lamps, Carbons and Illuminating Bodies hitherto employed.* By Dr. ALFRED RITTER VON URBANITZKY. (Das elektrische Licht und die hierzu angewandten Lampen, Kohlen, und Beleuchtungskörper.) Third Edition. Vienna, Pest, Leipzig: Hartleben.

When a reviewer has found it possible to make favourable mention of a book it is always satisfactory for him to find that the public has endorsed his judgment so that successive editions of the work have been found needful.

In the present case a thorough revision and rearrangement of the subject matter has been found necessary in consequence of the rapid progress of electro-technics. The present edition is in many respects a simplification. Thanks to the unceasing activity which is being displayed both in the theoretical and the practical sphere, a new light has been thrown on many points which were till lately a subject of doubt and controversy. The description of glow lamps, which in the two earlier editions occupied merely 13 pp., now extends to upwards of 50, although the author evidently eschews superfluous verbiage.

We think that electricians who already possess a copy of the first or second edition, will find it advantageous to add the present impression to their libraries.

## LINEFF'S ELECTRIC TRACTION SYSTEM.

THIS letter came in too late to take its place in our correspondence columns:—In your issue of last week you published a letter of Mr. Frank B. Lea on my new magnetic conductor.

I am much pleased with the impartiality of Mr. Lea's criticism, although I must beg leave to differ in several of the points touched upon.

To begin with, his fear that "the insulated rail sections would sink so much that they would be in contact at many points along the line with the internal conductor" is perfectly groundless. For this to happen two things are necessary: the breaking of the earthenware supports or tiles which are embedded in asphalt, and also the crushing of the latter around the exposed and blind rails. Considering that the crushing strain of both materials is very high, it is easy to demonstrate that the power required to crush in the conductor is enormous, compared even with the severe mechanical test applied by Mr. G. Kapp (heavy steam roller), and the existence of such heavy weights in public streets is simply out of the question. A good concrete bed for the conductor is, of course, a condition *sine qua non*; but so it is for the running rails and the paving between them, and consequently this does not involve any extra outlay. Sketches of my conductor have appeared in most of the technical papers, and Mr. Lea will be able to judge for himself that very careful attention has been paid to the mechanical requirements. The magnetic rails are not only supported by such a strong material as earthenware embedded in asphalt, but are, moreover, securely interlocked by the latter, and all engineers know what a capital foundation for machinery this material makes, and how it takes up vibrations and strains.

If Mr. Lea had been present at an experiment I made with two lengths of magnetic rails imbedded in asphalt, when it took about four hours for two men with sledge hammers to detach the rails from the asphalt, he would have more confidence in the resisting power of my conductor.

Mr. Lea is quite right in refusing to recognise any similarity between the action of a heavy steam roller with the "ceaseless wear and tear of every day traffic;" but he is wrong in assuming that the latter is more dangerous to the efficiency of my sealed conductor. The experiments I have made in this direction lead me to conclude that this ceaseless rolling of cart-wheels will keep the asphalt round the rails compressed, thus preventing any possibility of leakage. Moreover, the wear and tear of asphalt is a quantity well known, and large cities, like Paris and Berlin, use it almost exclusively for paving.

With all respects to Mr. Lea's electrical training, I must decidedly contest his criticism as regards surface leakage. The well-known theory about the weakest link of a chain cannot be applied to surface leakage, as the latter does not depend on the quality of insulating material, but merely on the state of dryness, or otherwise, of the surface. Telegraph engineers know the fact well, and while getting in dry weather an insulation resistance of, say 20–30 megohms per mile, this resistance will fall to perhaps 200,000 ohms in wet weather. Of course, it would be absurd to record the yearly average insulation of the line either at the former or the latter figures, but it must be some mean quantity depending on the number of wet and dry days during the year.

About the joke as to the extraordinary weight of passengers in Mr. Kapp's calculations, I will say nothing. I should like only to point out that the car referred to was intended to accommodate 52 passengers, similar to those used by the West Metropolitan Tramway Company. If Mr. Lea will take into account the extra weight of car and motor necessary for traction by accumulators, he will find the weight of the latter mentioned by Mr. Kapp quite in accordance both with American and continental practice.

In conclusion, I must add that, if one had to mind

all friendly "fears" and "doubts," no invention would be possible. But I believe Mr. Lea wishes me well, and declares that no one would be more pleased than himself if such fears should prove illusory in actual practice, and this I hope to demonstrate to him very shortly.

ALEX. L. LINEFF.

ELECTRICAL TRADES SECTION LONDON  
CHAMBER OF COMMERCE.

A MEETING of the section was held at Botolph House on Wednesday, Mr. Crompton in the chair.

The first business before the meeting was to receive the resignation of Mr. Trotter as technical correspondent.

Mr. CROMPTON regretted very much that Mr. Trotter, on account of other duties, was obliged to withdraw from the office. His position as chairman had only been made possible by the capability of Mr. Trotter. He thought the thanks of the section were due to him for the able manner in which he carried out technical matters relating to the section.

A vote of thanks was passed, and Mr. TROTTER responded.

Major FLOOD PAGE said with reference to the appointment of a successor, he would have a proposal to lay before the section at the next meeting; in the meantime, he hoped the matter would be left over.

A resolution was passed in accordance with the wishes of that gentleman.

## OVERHEAD WIRES.

The section next considered the reply of the Board of Trade to the resolution passed by it at its last meeting with reference to clauses 9 and 12 of the Board of Trade regulations relating to the insulation, &c., of cables, and the suspension of conductors.

The CHAIRMAN incidentally remarked that the effect of the regulations had been, in one case, to run up the cost of a certain cable used for street lighting from £28 to £75 per mile. The reply of the Board of Trade amounted to a blank refusal to reconsider the matter.

Major FLOOD PAGE moved, and it was resolved, that the chairman be requested to draw up a short statement of the disadvantages and hindrances to the electrical trade of some of the Board of Trade regulations, and to send it to the secretary of the Institution of Electrical Engineers, together with the resolution of the section already signed, and a copy of the Board of Trade's letter, and a request for the appointment of a committee of the Institution with a view to meeting a committee of the section for the purpose of considering and inducing the Board of Trade to reopen the matter.

## PATENT LAW REFORM.

The report of the Manchester Chamber of Commerce was laid before the section. The report points out that the Patent Law at present allows of considerable abuse, *i.e.*, bogus inventions are very frequently patented in order to prevent the possibility of other inventions of a similar class; and it suggests that the law should be so amended as to make such abuse impossible.

The SECRETARY said the Chemical Section of the Chamber had considered the matter, and recommended the appointment by the council of a representative committee of the various sections interested in the matter, with a view to making some practical suggestions.

A MEMBER thought the law of disclaimer should be abolished.

Another MEMBER pointed out that the section was only interested to a very small degree.

It was resolved to address the council to the effect that should it think fit to appoint a committee, the Electrical Section would assist as far as it can, and be prepared to appoint delegates.

## THE FRANKFORT ELECTRICAL EXHIBITION.

The SECRETARY laid on the table a copy of the regulations.

Major FLOOD PAGE took occasion to point out that the date for sending in exhibits has been extended in favour of foreign exhibitors to September 30th.

## THE EDINBURGH ELECTRICAL EXHIBITION.

The SECRETARY read a letter from the committee, requesting the section to send in the names of jurors nominated by it.

It was resolved to address the committee something to the following effect:—The Section regrets that the committee of the Edinburgh Electrical Exhibition did not avail itself of the opportunity of the presence of the Institution of Electrical Engineers in Edinburgh to confer as regards the appointing of jurors; that as the section is informed that it is not the intention of the Institution of Electrical Engineers to appoint jurors, it regrets that it will be unable to do so; and further, the section points out the inconvenience arising from the lateness of the application, when most of the members have already made arrangements for their holidays, &c.

## RAILWAY RATES.

Mr. TROTTER produced the following draft classification issued by the Board of Trade for those items of the merchandise traffic which specially concern the electric trade, and observed that on the whole the trade had reason to be satisfied.

	Old classification.	Cleaning House.	Class in de osited schedule.	Class proposed by Chamber of Commerce	Classes recommended by Board of Trade.

## THE LIGHTING OF SOFIA.

The secretary produced a letter from the Foreign Office, the purport of which will be found in another place. The proceedings then terminated.

**Electric Light in West Africa.**—We are informed that the first installation of electric light in West Africa was started on May the 31st last, at the Gie Apponto gold mine on the Gold Coast. A Siemens compound dynamo supplies 15 lights to the stamp mill house, engines and boilers. The installation, which has caused a great sensation in the colony, was set up by Mr. J. A. R. Milton, formerly with Messrs. Woodhouse and Rawson.

## NOTES.

**Electric Lighting at Bromley.**—The local syndicate for the electric public lighting at Bromley, Kent, has resolved that it will not favour any particular company in the carrying out of their scheme, but will employ its own engineer to get out estimates and then invite tenders from some of the best firms.

**Bristol and the Electric Light.**—The question of the desirability of adopting the electric light for the illumination of the streets is occupying a good deal of attention at Bristol. The Electric Lighting Committee recently visited London and Chelmsford, and at their last meeting decided to proceed to Bradford.

**Electric Lighting at Woking.**—A public meeting was held on Tuesday evening to consider the desirability of lighting the town by electricity. After a discussion a vote was taken, 24 against 5 being in favour of lighting the town. It is probable that a further meeting of ratepayers will be held on the subject.

**Lighting of the Hotel Metropole, Brighton.**—With reference to Messrs. Verity's letter, Messrs. Benham and Froud say, "We wish to take the credit for nothing more nor less than the work we actually executed. If you will kindly refer to the memorandum we sent you, with our brief notice, you will see we describe them as the 'principal fittings,' and so undoubtedly they are, comprising (1) the 'electric sunlights' for the whole of the magnificent suite of three public dining rooms; (2) the whole of the private sitting room electroliers; (3) the principal vestibule electroliers; (4) several hundreds of portable table pillars for the bed rooms. We have not stopped to enquire whether one, four, or forty other houses also supplied fittings, nor have we stated that the designs were ours, the drawings having, in point of fact, being supplied to us by Mr. Holland."

**Electric Lighting in St. Pancras.**—A special meeting of the St. Pancras Vestry was held on Wednesday night to consider the report of the committee mentioned in our last and present issues. An amendment was proposed, referring the report back, but this was negatived, and the report was finally adopted.

**New Spanish Cable.**—The *Standard* says that the new Spanish Minister of War, General Azcarraga, has resolved to proceed at once with the laying of a telegraph cable between Spain and her stations on the coast of Morocco.

**Appointment.**—We hear that Mr. A. R. Bennett, formerly of the National Telephone Company, has been appointed engineer-in-chief to the Mutual Telephone Company.

**Electric Traction at Chiswick.**—The members of the Chiswick and Brentford Local Boards have expressed themselves so satisfied with the Lineff magnetic conductor that they have given their consent to its adoption on such portions of the West Metropolitan Tramways as are under their respective jurisdictions. The only remaining local authority whose consent must be obtained is the Hammersmith Vestry, to whom two alternative schemes will at once be submitted. The first refers to the application of the Lineff system to the line from Young's corner to the Uxbridge Road Station terminus; and the second from Young's corner to Hammersmith Broadway. As soon as their consent is given, the work of laying down the conductor from Kew Bridge either to Uxbridge Road station or to the Broadway will be at once proceeded with. The West Metropolitan Tramway Company has instructed Mr. C. Nicholson Lailey to prepare a report on the reconstruction of the line.

**Central Station at Verona.**—A central electric light station is now being erected in Verona, according to the plans of Mr. Eugenio Vitale, the Italian representative of Messrs. Schücker and Co., of Nuremberg. The station will be completed in a few months, and will have a capacity of 3,000 lamps. Of these, 30 arc and 1,200 incandescent lamps are to be put into operation this month. The three-wire system of distribution, in conjunction with feeders, has been adopted, the conductors being placed overhead. The steam plant has been supplied by Messrs. Tosi & Co., the conductors by Messrs. Pirelli & Felten and Guilleaume, and the electrical apparatus by Messrs. Schücker. The station is the property of a co-operative society.

**Lyons National and Colonial Exhibition, 1892.**—The project of a great national and colonial exhibition has just been adopted in France, to take place in Lyons during the year 1892. Two sections will be international: silk and electricity.

**English and French Submarine Cables.**—Mr. Raikes, in the House of Commons, in reply to Mr. Henniker Heaton said: I have to state that a substantial profit will no doubt result from the purchase of the submarine cables between this country and the Continent, but it would be premature at present to estimate the amount of that profit in view of the condition of the cables. As the House is aware, some of these cables are very old, and it is possible that before long a considerable expenditure may have to be incurred in renewals. Not only so, but the necessity for additional plant has arisen, and a large sum will be spent in the course of the current financial year on a new cable and land line. The number of words in Anglo-French telegrams has risen from 13,376,333 in the year to March 31st, 1889, to 15,495,791 in the year to March 31st last. Other telegrams have passed over the Anglo-French cables, but I am not able to give separate particulars with regard to them. In answer to a further question by Mr. Henniker Heaton, Mr. Raikes said that he had no knowledge of what had passed in the French Chamber. It was possible that it might be necessary there to ask for a vote for a cable between France and England, but it was not necessary to ask Parliament for the money for a cable to France.

**The Institute of Medical Electricity, Limited.**—This Institute has been removed to larger and more commodious premises at 35, Fitzroy Square, W. Increasing work and the need for being nearer the great medical centres of Harley Street and Wimpole Street induced the directors to make the change. They have taken one of the old-fashioned substantial residences on the Grafton Street side of the square, and it contains many large, light, and airy rooms, well adapted to the purposes of the institute. The drainage has been entirely renewed, and the house decorated from attic to basement. The apparatus has been carefully removed from the old quarters at 24A, Regent Street, and new has been added to it, so that greater facilities for electrical treatment are now available. We understand that increasing use is being made of treatment by "cataphoric medication," or the passage of drug solutions through the skin by means of electric currents. This method of obtaining strongly localised action has been developed from its experimental stage, and first brought into practical use at the institute under the auspices of Dr. Arthur Harries and Mr. H. Newman Lawrence. It has already proved very successful.

**Edison's Greatest Work.**—Dr. Lassar stated at the Medical Congress, now held in Berlin, that Mr. Edison intended, through his medical adviser, to communicate a novelty in the shape of an application of electricity for the removal of stone. This will be glad news, if true, for the operation for this disease is reckoned amongst the most painful; and if Edison completes this work, he will have achieved his greatest success, for the name of him who has alleviated pain goes down to posterity ever blessed.

**Tenders for Electric Lighting.**—Estimates are requested for lighting the public streets and buildings in Helston (Cornwall) by gas, oil, or electric lights, per annum, for the Town Council. Tenders to be sent to Mr. J. G. Plomer, town clerk, by 16th inst.

**A Record in Dividends.**—The *Gazette* notifies the payment from the estate of the late Mr. Ex-Alderman Hadley, 5, Knight-riding Street, of a first and final dividend of one-sixth of a penny. The connection of Mr. Hadley some years ago with a submarine cable scheme will probably be still fresh in the memories of our readers.

**Opposition to Electric Lighting Poles.**—The Fareham Electric Light Company, having been made the subject of an indictment in respect of the poles which they have recently erected in the town, a mass meeting of ratepayers was held on Tuesday. A resolution was passed expressing sympathy with the company in its endeavours to introduce into the town a better and a purer light, and condemning the action of a privileged few in endeavouring to thwart the wishes of the ratepayers. The electric light company, it may be added, have entered into a contract with the Local Board, under which they are to light the streets of the town for a period of three years for the annual sum of £500, or £30 less than the price at present paid for gas. This matter has been referred to on another page.

**Prevention of Vibration in Lamp Filaments.**—To prevent excessive vibration of filaments of incandescent lamps, a method has been employed in which the loop end of the filament is steadied between metallic posts set into the glass bulb. When, however, this arrangement is used, frequent contact between the filament and these metallic posts soon weakens the former, removing, as it does, small particles at a time, and the life of the filament is materially reduced. It has also been found that the filaments, by their frequent contact with metallic posts, form grooves in the latter by melting away the material. In experiments made with the view of producing stops which will effectually accomplish the desired result, and at the same time insure the full life of the filament, George R. Lean, of Boston, has found that the stop or stops must be made of material which will not melt and that is non-combustible; and also that a stop composed of the same material of which the filament is made is best suited for the purpose. He, therefore, provides stops of carbon, they being secured to the apex of the bulb, and located adjacent to each other to receive between them the filament. When the air is exhausted from the bulb, a small short tube of glass is fitted in the hole at the end. The outer end of this tube is afterwards sealed. To secure the stops in place, the inner end of this tube is closed, and the stops are secured in the closed end.

**Pole-Finding Paper.**—Since the time when we first had occasion to notice Wilke's pole-finding paper, Dr. Oscar May, of Frankfort, who is the sole proprietor and maker of the paper, has improved the form in which it is issued to the public. No change has been made in the material itself, but the sheets of prepared paper being bound up with a stiff cover, instead of a limp paper back, renders its present form of issue much more convenient for carrying in the pocket, at the same time giving more protection to the paper, and thus preserving it in good working order for a longer period. Bound up with the pole-finding paper will be found instructions for its use, and claims as to its advantages over the expensive instruments which have hitherto been in general use for the purpose of detecting the direction in which a current is flowing. The indications being absolutely correct, even with as low a potential as a single volt, Wilke's P.F.P. affords a handy and speedy means of determining the direction of a current, or for the detection of leakage in conductors and other kindred faults. The paper can be obtained from Berend & Co., Fore Street, E.C., the sole representative of Dr. May in this country.

**The Southend Electric Tramway.**—Messrs. Crompton and Co., Limited, are running an electric tramcar along the pier at Southend. The engine, boiler and dynamo are situated under the arches near the entrance of the pier, and the current is conducted along the central rail for three-quarters of a mile down the pier. The car holds about 40 persons, and travels at the rate of about sixteen miles an hour, doing, in some three and a half minutes, the journey which takes nearly fifteen minutes by horse traction. The line, which has been carried out in a very expeditious manner, was certified by Dr. Hopkinson on Friday last, when he expressed himself highly gratified at the result. On Saturday afternoon, after a few trial runs, it was handed over to the Local Board for public use at four o'clock. Immediately, large numbers of people availed themselves of it, and all day on Monday (Bank Holiday) the car was well patronised. As this is a highly satisfactory exhibition of electric traction situated a short distance from London, it will no doubt be visited by everybody interested in this particular work. Messrs. Crompton inform us that they are willing to give any information to those who require it and will call at their offices before proceeding to Southend.

**The Lane-Fox Patents.**—It seems that Mr. Lane-Fox and his advisers are not going to get their own way without a struggle; perhaps not even then. Sir Frederick Bramwell, Mr. Swinburne, and Mr. Kapp are all agreed that the claims of the Lane-Fox Company cannot be sustained, and the Kensington and Knightsbridge Electric Lighting Company has opened communications with several others for the purpose of co-operating together for the formation of a defence association. The proposed basis for this, which we should be glad to see carried out, is as follows:—1. To defend any action that may be brought against any of them by the Lane-Fox Electrical Company, who are threatening to commence actions in respect of the letters patent owned by them, and alleged to cover the system of supply above mentioned. 2. To take such advice and collect such information as may be necessary for the protection of the rights of the several members of the association to use the system of supply above mentioned. 3. Supply companies to subscribe a minimum of £50, contractors £25, and owners of private installations £10, to be called up as required; this would entitle members, thus constituted, to claim that the association should defend any action to the extent of the funds subscribed, and any additional amount which may, from time to time, be voted in general meeting, which might be brought against them by the Lane-Fox Electrical Company, in connection with the above-named claims. 4. Should further funds be required, the members are to be called upon to subscribe, in the ratio of the sums above mentioned, according to their respective denominations. 5. Any member of the association may retire at any time, in which event this association shall no longer be under any liability to defend any action which may have been brought, or may be brought, against the member in question.

**What the Americans Say.**—The *India Rubber World* states that Mr. Ferranti has surmounted the difficulty of jointing cables to carry 10,000 volts. This is scarcely borne out by a note which appeared in our last issue.

**The Phonographic Doll.**—The *Financial News* of Wednesday says:—"Rumours being current that there was some hitch in connection with the Phonographic Doll Company, our representative made inquiries at the offices of the company yesterday, and was informed by the secretary that the statement as to the company having been withdrawn from the public was incorrect. This gentleman declined to give any further information, and in reply to a question as to whether the company had gone to allotment, remarked that he was not going to be 'pumped.'"

**The Manufacture of Cables in America.**—Of the manufacture of cables in America, a rubber journal of that country says:—"Some day, perhaps, America will take a hand in submarine cable work, but the day seems far distant, as she looks on so complacently while cables are being landed on her shores or on those of neighbouring countries, and makes no attempt at participating in the labour and the profits."

**The Etiquette of Journalism.**—We have noticed from time to time complaints emanating from our English contemporaries respecting the cool manner in which articles have been abstracted from their columns and reproduced across the herring pond as original matter. We, too, on various occasions, have detected many productions of our own appearing in American journals as editorials, but we have rarely come across a more audacious case of piracy than that of which the *Electro-Mechanic* has been guilty, viz., the publication of our leading article on "Lightning Protectors" from the REVIEW of May 16th, without the slightest recognition of its origin. We are fain to believe that the source of papers which English journalists think may prove interesting to their readers is invariably acknowledged, unless through some oversight of rare occurrence, but we cannot give the American technical press credit for the same honesty of purpose.

**Kemmler's Execution.**—The following particulars of the end of Kemmler, the first man to suffer the extreme penalty of the law by death from an electrical shock, were telegraphed, on the 6th inst., to the *Standard*:—"The convict Kemmler was to-day executed by electricity at Auburn Prison, New York. The execution, which took place at seven o'clock in the morning, was a trying spectacle, as, owing either to imperfect regulation of the strength of the currents or faulty contact of the electrodes, the convict's death was not instantaneous. There were present in the chamber where the execution was carried out twenty-six persons, including several physicians, scientists, and officials. The unhappy man showed great nerve, placing and adjusting himself in the execution chair with perfect calmness. The lethal shock continued for eighteen seconds. Two minutes after the current was suspended there were evidences of respiration. As soon as possible the current was renewed and then cut off, but again respiration was evident, and a minute or two afterwards saliva issued from the mouth, the chest heaved, and a wheezing sound came from the throat. The shock was then applied for the third time, and Kemmler was pronounced to be dead. The physicians say that he was unconscious from the moment of the first shock. Smoke appeared at the back of the body, where the flesh was burnt by the intensity of the current. The voltage at the first shock was 1800. The duration of the first shock was seventeen seconds, after which it was supposed that Kemmler was dead. The spectators, however, were then horrified by the respirations being renewed, the entire body being racked in the efforts of the organs to resume their functions. The current was then started again. A convulsion was marked on the first application of the electric current, and the culprit was declared to be dead in 13 minutes from the first stroke. The flesh on the back was burned, and there was also a spot on the top of the head. The doctors who made the autopsy agree that unconsciousness set in immediately, and declare that death was apparently painless, notwithstanding the slight defects in the apparatus, which required a second contact to ensure death. There was a considerable charring of the body at the points of contact of the electrodes, and a minute hæmorrhage was found in the serous membranes and ventricles of the brain. The blood was fluid and dark in longitudinal sinuses, corresponding with the region of contact. The blood was carbonised, and there was a decided change in the consistency and colour of the brain, corresponding with the point of contact. Destructive changes in the blood corpuscles were noted. The consensus of

opinion of the spectators was that execution by means of electricity is a failure, even if properly carried out, but that it was not instantly successful to-day because of the low voltage, or owing to a too short application of the current, or for both reasons. Had the current been maintained for 30 or 45 seconds at the first application, it is believed that there would have been no possible question of a satisfactory result.

Telegrams from New York yesterday read as follows:—"Further particulars regarding the execution by electricity show that signs of dissatisfaction were made by the spectators when on the application of the third current smoke was seen to be curling from Kemmler's back. The warder, therefore, again gave a signal to open the switch, when the culprit's body in the chair was surcharged with four distinct shocks. After this no further movement was observed. Dr. Shrady, the editor of the *Medical Record*, has written a letter, in which he says that nothing has been gained over the ordinary method of execution. Science has triumphed, but the question of the humanity of the act is still an open one. The method requires elaborate preparations, involves the manufacture of new machinery, and, moreover, may endanger the lives of the executioners, and even the spectators. All the morning papers publish articles upon the execution, and the opinion is generally expressed that the law authorising execution by electricity will be repealed by the New York Legislature at an early date. It is also held that the various criminals now waiting execution in the New York gaols should be granted a stay of their sentences until the law has been repealed.

**Trial of an Electrician for Manslaughter.**—At Bristol, on Wednesday, an amateur cyclist, named Henry Askham, electrical engineer, was tried before Mr. Justice Denman, charged with the manslaughter of Thomas Davis, at Pensford Hill, in May last. In defence, it was contended that the prisoner could not be held accountable for Davis moving into the track of the machine. The jury, after retiring, returned a verdict of not guilty, and the Judge, in discharging Askham, suggested that he should do something to help the widow of deceased.

**Electrical Aids to Sport.**—Advertisements have recently been seen in the daily press to show that Mr. Gunn, the famous Nottingham cricketer, made his recent memorable score against the Australians by the aid of a "Harness's electropathic belt." Judging from the comparatively few runs he has since made, we can only conclude that his long innings at "Lord's" robbed that belt of its virtue. At all events, if Mr. Gunn could only refer to some back numbers of the REVIEW we feel sure he would do nothing less than explode.

**Exhibition at Frankfort-on-the-Maine.**—Appended are a few of the rules for the forthcoming exhibition:—The exhibition will last five months; it will be opened on May 15th, 1891, and closed on October 15th, 1891, the committee reserving themselves the right of altering above dates. Only such objects will be admitted to the exhibition which can be brought under the following heads:—Motors for electrotechnical purposes, as steam, water, air or gas motors, with the necessary appliances for producing steam, &c.; production of electricity; transmission of electricity, with all transmitting and supplementary apparatus; accumulating and transforming apparatus; transmission of electric power with a view to industrial purposes; electric light, with special subdivision for fittings of all kinds; telegraphy and telephony; electric signalling, as applied to railways, mines, nautical and military matters and private houses; protection against fire, thieves, and lightning; electro-metallurgy and electrolysis; measuring instruments, scientific apparatus, acoustic and optical instruments relating to electricity, school-teaching apparatus; electricity as applied in medicine and surgery; electrotechnical literature. Mention must be made whether the objects are for sale and at what price, and if

required the words "for sale" must be affixed. Cost of fire insurance to be borne by the exhibitors. Insurance cared for by the committee, the value to be conscientiously given on the schedule of applications. The committee provide working power and main transmissions, as well as the necessary quantity of electricity, steam, water, and gas. Should the exhibition close with a surplus, up to one-half of the same will be applied to a total or partial repayment of expenses incurred for space and power by exhibitors. Exhibitors are bound to insulate all wires for electric currents belonging to their exhibits, and to guard the same in such a way as to exclude all possible danger to the public and the buildings. The laying of cables or setting up of wires can be done by special permission of the committee only and under the supervision of the latter's employees. Whenever the committee should think fit, such cables are to be fixed by their own workpeople at the exhibitor's charge. All applications and communications to be addressed to "An den Vorstand der Elektrotechnischen Ausstellung, Frankfort-on-the-Maine."

**American Patent Office.**—The American Patent Office has recently given an example of its method of work. Two patents issued on the same day read as follows:—"Claim 1, Patent 432,131, dated July 15th, 1890, reads:—1. In a current regulator or rheostat, the combination of a surface of non-conducting material coated with a conducting substance, and in which the conductivity decreases from one place upon the surface to another, means for connecting a conductor with a portion of the conducting material of greatest conducting power, and a movable contact device movable over the contact surface, and formed with a series of flexible fingers resting upon said conducting material. Claim 1, Patent 432,279, dated July 15th, 1890, reads:—1. In a current regulator or rheostat, the combination of a surface of non-conducting material, provided with a coating of conducting substance which gradually decreases in breadth from one point to another, means to connect a conductor with said coating of conducting substance at the point of its greatest breadth, and a contact-piece movable over said conducting surface with a contact face of greater width than the decreasing breadths of the conducting surface, whereby as said contact piece is moved over said conducting surface the area of its contact face in contact with the conducting surface will gradually decrease." We fear Americans beat us in many things; in patents we are miles behind.

#### NEW COMPANY REGISTERED.

**Grange Syndicate, Limited.**—Capital £2,000 in £5 shares. Object: To develop and experiment upon Groth's Electric Tanning System in conjunction with the patentee upon terms of an agreement with Mr. L. A. Groth. Signatories (with 1 share each): L. A. Groth, C.E., 3, Tokenhouse Buildings; T. W. Maule, L.C.C., 12, The Grange, Bermondsey; F. Fleming, Halifax; C. Clark, 20, Great St. Helens; A. Vinos, Sevenoaks; F. Whitcomb, 27, Endsleigh Gardens, N.W.; L. Tucker, Victoria Mansions, Westminster. Registered 1st inst., without special articles, by Courtenay, Croome and Company, 9, Gracechurch Street.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Lancashire and Yorkshire Electric Lighting Company, Limited.**—The annual return of this company made up to the 9th ult. was filed 30th ult. The nominal capital is £100,000 in £5 shares. 127 shares are taken up, and £2 10s. per share has been called thereupon. The calls paid amount to £315 and unpaid to £2 10s.

**Manchester Edison-Swan Company, Limited.**—The annual return of this company made up to the 28th ult. was filed 29th ult. The nominal capital is £550,000 divided into 50,000 "A" shares of £9 each, and 10,000 "B" shares of £10; 20,000 of the former and the whole of the latter are taken up. Upon each "A" share the sum of £1 has been called, and upon each "B" share £10 has been called. The calls paid amount to £20,000 on the "A" shares and £100,000 upon the "B" shares.

**Patent Electric Fire Lighter Company, Limited.**—At an extraordinary general meeting of this company, held at the offices of Messrs. Heath, Parker & Co., 3, New London Street, Mark Lane, on June 23rd, it was resolved to wind up voluntarily, Mr. Wm. Finch being appointed liquidator at a remuneration of £10, with instruction to transfer the business to a new company to be called the New Electric Fire Lighter Company, Limited. The resolution was confirmed on the 10th ult., and duly registered on the 31st ult.

**Key's Electric Company, Limited.**—The statutory return of this company made up to the 24th ult., was filed on the 30th ult. The nominal capital is £15,600 in 3,000 ordinary shares of £5 each, and 600 founders' shares of £1 each, the whole of the ordinary shares and 450 founders' shares are taken up, upon the former 10s. per share has been called, and the full amount upon the latter. The calls paid amount to £1,896, and unpaid upon founders' shares £54. Registered office, 122 and 124, Charing Cross Road.

**New Portable Electric Lamp and Power Syndicate, Limited (in liquidation).**—The registered office of this company is now situate at 43, Coleman Street.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Anglo-American Telegraph Company, Limited.

THE Marquis of Tweeddale presided in the absence of the Chairman, Viscount Monck, at the ordinary general meeting of the shareholders, held at Winchester House, last Friday, and in presenting the report (printed in our last issue), and accounts for the year ending 30th June, 1890, said the increase shown on traffic receipts, viz., £2,025 over the corresponding period of last year was satisfactory, because, in the first place, the period was the least profitable, and, in the second place, because he believed the increase was due mainly to the opening of three new offices in New York, which had brought the company in closer contact with the telegraphing public of that city. The revenue from those offices would no doubt be further increased as they became better known. It was also satisfactory to note that the whole of the company's cables were in good condition. There had been fewer faults to repair, which was in a great measure owing to the Duxbury cable (referred to on previous occasions), so that the expectations formed had been fully realised. Moreover, all the cables of the pool were in equally good order. One of the cables of the Western Union Company, after having been out of order for something like 13 months, was now repaired, at the great depth of some 2,500 fathoms. The company's traffic had been conducted with the usual accuracy and efficiency, and, he was glad to add, at a speed higher than had been achieved by any other Atlantic company. The directors had been, for the last six months, expecting a settlement of the dispute with the Paris and New York Telegraph Company, which had not yet been arrived at, and he had no notion as to what the decision would ultimately be. They observed that the company's working expenses had increased by about £5,692. The increase was almost entirely made up of one figure, viz., £4,352, spent in the establishing the three offices referred to, the balance being composed of a number of small items calling for no particular notice. Expenditure on repairs showed an excess of £2,023; that was really a satisfactory feature, since the repairs had been entirely of a character chargeable to revenue. For renewals, the expenditure had been extremely small, and amounted to £552 19s. 5d. only, consequently the whole of the interest upon the renewal fund had been credited to that fund, making it £968,861 18s. 7d., the market value of which was about £50,000 more; in fact, the renewal fund amounted to over a million. The terms under which the company acquired the Brest-Salcombe cable from the liquidators of the Submarine Telegraph Company were altogether satisfactory. He moved the adoption of the report and accounts, and was seconded by Sir Jas. Anderson.

A Shareholder was sorry that the whole of the interest had been credited to the renewal fund. There ought to be some limit to the extent of that fund.

Another Shareholder reminded the meeting that some time ago it was tacitly agreed that the renewal fund must not exceed one million. He thought that on the next occasion the directors

should abstain from adding interest to that fund, since, with the value of the investments, it already exceeded the limit agreed upon.

Another Shareholder suggested that henceforward the whole of the renewal fund should be appropriated to the deferred shareholders, seeing that it had come entirely out of their pockets. (Cries of dissent.)

The Chairman was aware of the agreement referred to. It was most important the company should have an ample renewal fund. Its cables were growing older, and considerable sums might soon have to be spent for renewals.

The motion to adopt the report and accounts was carried, and the meeting dissolved.

### City and South London Railway Company (late City of London and Southwark Subway Company).

THE report of directors to the shareholders at the twelfth half-yearly ordinary meeting of the company, to be held at Winchester House, next Tuesday, at 12 o'clock noon states:—

During the past half-year both of the tunnels have been completed, the whole of the permanent way laid, and the underground stations finished with the exception of tiling, painting, and other small matters. The surface stations and the lifts are rapidly approaching completion, and the hydraulic pipes and electric conductors are laid throughout. At Stockwell depot the inclined road leading to the tunnels is finished and in use, the two engines and dynamos for the electric power are completed, and the third or reserve engine and dynamo is nearly ready, the three engines in connection with the hydraulic power for working the lifts are also ready, and the engine house and carriage stores are roofed in. A portion of the rolling stock is ready for delivery, and it is expected the railway will be opened for public traffic at an early date.

The Bill for the extension of the line to Clapham has passed through Parliament, and received the Royal assent. By it the name of the company is changed to the "City and South London Railway Company."

The Bill referred to in the last report, and known as the Central London Railway Bill was thrown out in the House of Lords. Your directors will have to consider how far some of the advantages proposed by that Bill could be usefully provided by this company without the objections urged against that measure.

To meet the wishes of many of the larger shareholders notice has been given of a resolution to convert the share capital of the company into stock, so as to facilitate its transfer.

Mr. J. H. Greathead, M.I.C.E., the engineer, reports as follows:—

During the last half-year the remaining length of tunnel through the wet strata at Stockwell has been completed, and the permanent way and hydraulic pipes have been laid throughout both sections of the line.

With the exception of some small matters, such as portions of the glazed tiling and painting, the underground works from the City to Stockwell have been finished, and the buildings on the surface are in a forward state.

The lifts and signalling arrangements are approaching completion.

The engines for generating the hydraulic power, and the boilers for working all the machinery, are ready for starting.

The electric working conductor has been fixed throughout; two of the three electric generating engines have been erected; delivery of the locomotives has commenced, and some of the carriages are ready for delivery.

### The London Road Car Company.

At the half-yearly meeting of the shareholders of the London Road Car Company (Limited), at the City Terminus Hotel, Cannon Street, on Tuesday last, under the presidency of Lieut.-Col. C. F. Colville,

Mr. George Offer in the course of a discussion which ensued upon the Chairman's motion for the adoption of the report said that at a previous meeting he had made allusion to the subject of the progress made with electrical traction. His remarks, however, were met with derisive laughter from some of the shareholders, and one of the directors went so far as to venture into prophesy, telling the meeting that not in their time would they see omnibuses propelled by electricity. Now, he (Mr. Offer) in justice to himself and as a warning to his jubilant friend, Mr. Hodgson, would like to read an account of what had recently taken place showing that in London the electrical omnibus was a fact. Only the other day there was seen in the afternoon coming down St. Martin's Lane, into Trafalgar Square, the first of the new line of the electrical omnibuses, which was driven by Mr. Ward, the managing director. It came down the street with one passenger inside, and two outside, going at a rattling pace, and went in and out the ordinary traffic without difficulty. Mr. Offer said that when he spoke on the subject at the last half-yearly meeting he did so with such a knowledge of the facts that he was able to form an opinion on it. He now said, therefore, that the day would come and at a not very distant period, when all their anxieties about the price of forage, and the health of their horses, would be at an end. He was pleased that the meeting had not that day met his remarks with derisive laughter, and he hoped they would go a step further, and when it came to the time to make an addition to the board of directors, that they would consider the

qualifications of their candidates in the direction of their possession of some knowledge of electrical traction. (Hear, hear, and laughter.)

The Chairman, in briefly replying to Mr. Offor, said that he (the speaker) did not think they need discuss the question of electrical omnibuses. There was no doubt they would keep their eyes open when these 'buses appeared, but until then they were unable to do so.

### The North Metropolitan Tramways Company.

MR. GEORGE RICHARDSON presided on Wednesday at the 41st half-yearly meeting of the North Metropolitan Tramways Company, held at Cannon Street Hotel. The report contained the following paragraphs:—"The Bill introduced into Parliament this year for authorising an increase of the share capital of the company to the extent of £100,000, and also for the use of electricity as a motive power for propelling the cars throughout the system, received the Royal Assent July 4th, 1890. Application has been made to the local authorities for consent to work some of their lines by this power." "The arrangements entered into with the General Electric Power and Traction Company, Limited, referred to in the last report for working the cars on the Barking Road section are in operation, and during the last half-year they have run 44,047 miles."

The Chairman, in moving the adoption of the report, commented briefly on these particulars. He said that the company had lost no time in applying to the London County Council and the West Ham Board for permission to use electricity, they being the two corporations having jurisdiction in the place where the directors proposed to try it. They did not intend to devote any of their money to experiments with electricity. If any person would come forward and make the installation, they would receive all the assistance the company could give, so long as there was no risk of spoiling a good traffic. The line at Barking was working now, and they would see the result later on. It was worked by contract at 4½d. per mile. With regard to the use of electricity elsewhere, in the United States a large number of lines were working by electricity, chiefly on the overhead system. He was not aware whether they could ever have that in this country, as there were difficulties in the way—the streets were narrow, and they would have to contend with the prejudices of the people. There were other systems, but steam was nowhere, as could be seen by a comparison of their dividends with the dividends on the North London Tramways Company.

The report was afterwards adopted.

### The Cuba Submarine Telegraph Company.

THE directors' report and accounts for the half-year ending 30th June, 1889, were laid before the shareholders on their thirty-eighth general meeting, held at the company's offices, 53, Old Broad Street, E.C., on Wednesday last, Mr. Thomas Greenwood presiding.

The Chairman said the half-year had been a period of some little anxiety, but, on the whole, not by any means an unsatisfactory one. It was the second half of the first year of the reduced tariff; therefore, in making the comparison they must bear in mind that it was compared with the period when the rates were 25 per cent. higher. The shareholders would observe that the receipts were £23,671 in June, 1889, and £23,206 in June, 1890, a difference of only £465. Of course a larger number of messages had been carried. It sometimes happened that increased traffic was accompanied by additional working expenditure. That had not been so with the company; in fact, as compared with the previous corresponding half-year, it had saved £30. They might ask how it happened that the dividend was reduced from 9 to 8 per cent. The explanation was that during the last half-year an addition had been made to the undivided balance, whereas in the corresponding period of the previous year that balance underwent a large diminution, which would account for the missing £800. In the future they would compare what was fairly comparable—viz., the reduced rates in 1890-91 with the reduced rates in 1889-90. He was pleased to say that the receipts for July, the first month of the new half year, showed a comparative increase of nearly £150, which, if it continued, would mean an improvement for the whole year of some £900, or more than sufficient to make a dividend of 1 per cent. Provided the company was not interfered with by outside influences, there was no reason for supposing that its dividend would be further reduced. They were aware that a proposal was before the Spanish Government involving the making of another cable, *via* the North Coast, which, if made, must inevitably attract to it a large portion of the company's traffic, and, at the same time, the Spanish Government had made a representation to the various telegraphic companies located in the Spanish colonies with a view to still further reducing the rates. Having already made a large abatement, it seemed a little unfair, especially as the Spanish Government was consenting to the extension of a rival company's line almost parallel with theirs. He need scarcely say the board was not prepared to consent to any abatement so long as they were threatened with the new line, and so long as the abatement was not a general one. To return to the accounts, a comparatively small addition had been made to the reserve fund, owing to so much money having been spent on the company's cables; but they might console themselves with thinking that the repairs to the cables made a large addition to the reserve unnecessary. The expenditure on repairs had been larger

than in any previous half-year; they had now a complete duplicate system between Cienfuego and Santiago, and with the projected new cable between Batabano and Cienfuego, their system would be complete and in duplicate from end to end. Progress had been made with the new cable, and they might reasonably expect to hear of its completion before their next meeting. He moved the adoption of the report and accounts, and, in reply to a shareholder, explained that the steps the directors had ultimately thought fit to take legal action, with a view to setting aside the concession above referred to.

The motion was carried.

The Chairman next moved to declare dividends of 10 per cent. per annum, subject to income-tax, on the preference shares, and 8 per cent., free of tax, on the ordinary shares of the company, payable on and after the 7th inst.

The motion was carried unanimously. Mr. Alexander F. Low was re-elected a director, and Mr. John Gane reappointed auditor, and, with a vote of thanks to the board, the proceedings terminated.

### The Maxim-Weston Electric Company, Limited.

The shareholders, at an extraordinary general meeting held yesterday, after hearing a statement of the company's affairs during the past six months from Mr. Gooding, the chairman, have resolved to wind up the company voluntarily and have appointed Messrs. Marks and Hodgson liquidators. It seems the company started with a nominal capital of £40,000 or £50,000, of which only £14,000 was subscribed. The private meeting held a few weeks since to ascertain the feeling of the shareholders with regard to subscribing more money, resulted in the promise of some £1,500 by way of debentures, a sum not nearly sufficient in the directors' opinion, to carry on the concern. The company is just able to discharge its liabilities amounting to about £300. The plant at the works is estimated at £7,000 as a going concern. Under the circumstances it was natural to suggest a reconstruction and this was done by Mr. Marks, who observed that there was still a gigantic field of work open to the company in the way of lighting. The proposal, however, found no favour with the meeting. A full report of the meeting will appear in our next issue.

### The Berlin General Electricity Company.

The general meeting of the shareholders in the above company has just approved the increase of the share capital from 16,000,000 to 20,000,000 marks. The new shares are offered to the old shareholders at the price of 165 per cent. The issue has been guaranteed by a syndicate of bankers, who are to receive 5 per cent. for their guarantee. This increase of capital has been necessitated by the increasing extent of the company's business, it having now undertaken the working of the Halle Metropolitan Electric Railway, besides having concluded contracts with two other towns for the establishment of electric railways.

### Elmore's Patent Copper Depositing Company.

The *Financial Times*, of August 5th, devotes a long criticism to the company, which has now been in existence for more than 18 months, and yet, according to our contemporary, has done no genuine work. The earnings of the company from its factory seem to be absolutely non-existent. It is hardly possible to suppose, says the financial paper, that even the "docile race" of shareholders will take up another issue of wire shares at a premium, when they learn that the vendors only value their patents at less than one-fifth of the price charged for them.

**The Western Counties and South Wales Telephone Company, Limited.** whose head offices are at 16, High Street, Bristol, have posted dividend warrants for an interim dividend for the half-year ending 30th June last, on the preference shares of the company, at the rate of 6 per cent. per annum.

**The Pilsen, Joel and General Electric Light Company, Limited.**—A general meeting of the company will be held at the office of the liquidator, Mr. George Shead, 18, Laurence Pountney Hill, Cannon Street, E.C., the 5th September, 1890, at 11, when the liquidator's accounts, &c., will be produced.

**The Byng Telephone Company, Limited.**—It has been resolved to wind up the company voluntarily; Mr. John Philip Spencer, 48, Cullingwood Street, Newcastle-on-Tyne, is the liquidator.

### TRAFFIC RECEIPTS.

- The Cuba Submarine Telegraph Company, Limited. The receipts for the month of July were £1,150, as compared with £3,093 in the corresponding month of last year. The receipts for the month of April, estimated at £3,500, realised £3,624.
- The Direct Spanish Telegraph Company, Limited. The estimated receipts for the month of July were £3,016, against £1,677 in the corresponding period of last year.
- The Great Northern Telegraph Company, Limited. The receipts for the month of July amounted to £25,000; 1st January—31st July, 1890, £156,000; corresponding months 1889, £164,200; do. 1888, £156,000.
- The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending August 1st, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,921.
- The West Coast of America Telegraph Company, Limited. The gross earnings for the month of July, 1890, were £5,825.

## SHARE LIST OF ELECTRICAL COMPANIES.

MAGNETIC PROPERTIES OF ALLOYS OF  
NICKEL AND IRON.\*

By J. HOPKINSON, D.Sc., F.R.S.

Eight different alloys have been examined. The methods of experiment were the same as were detailed in my paper on "Magnetic and other Physical Properties of Iron at a High Temperature." The dimensions of the samples were also the same.

A. The following is the analysis of this sample:—

Fe.	Ni.	C.	Mn.	S.	P.
97.96	0.97	0.42	0.58	0.03	0.04 per cent.

In this case a magnetisation curve is all that I have obtained free from doubt; the sample was heated and its magnetisation determined at various temperatures for a force of 0.50, but the higher temperatures must be taken as a shade doubtful, as the secondary broke down before cooling, and I cannot be sure whether or not the resistance of the secondary may have changed.

Table I gives the results at the ordinary temperature for the material before heating.

TABLE I.

Magnetising force.	Induction.
0.06 ... ..	11
0.12 ... ..	29
0.26 ... ..	58
0.53 ... ..	122
1.07 ... ..	303
2.14 ... ..	995
4.7 ... ..	4,560
8.8 ... ..	9,151
16.8 ... ..	12,876
38.9 ... ..	15,651
270.0 ... ..	21,645

The only noteworthy features are that the coercive force is obviously somewhat considerable, and that the maximum induction is great—greater than that of the more nearly pure iron.

B. The following is the analysis of the sample:—

Fe.	Ni.	C.	Mn.	S.	P.	Si.
94.799	4.7	0.22	0.23	0.014	0.037	trace per cent.

We have here results of induction in terms of temperature for a magnetising force of 0.12. The experiment with rising temperature was made by simply observing with a watch the hour at which the temperature attained successive values whilst the piece was in the furnace; the cooling experiments were made in exactly the way described in "Phil. Trans." A, 1889, p. 463.

The most remarkable feature in this case is that the material has two critical temperatures, one at which it ceases to be magnetisable with increase of temperature, the other, and lower, at which it again becomes magnetisable as the temperatures fall, and that these temperatures differ by about 150° C. Between these temperatures, then, the material can exist in either of two states—a magnetisable and a non-magnetisable.

We may infer from the experiments that the latent heat liberated in cooling is about 150 times the heat liberated when the temperature of the material falls 1° C.

C. This alloy is very similar to the last; its analysis is:—

Fe.	Ni.	C.	Mn.	S.	P.
94.39	4.7	0.27	0.57	0.03	0.04 per cent.

In Table II. are given the results of observations of induction in terms of magnetising force at the ordinary temperature of the room.

TABLE II.

Magnetising Force.	Induction.
0.06 ... ..	14
0.12 ... ..	29
0.25 ... ..	60
0.52 ... ..	127
1.05 ... ..	294
2.10 ... ..	760
4.6 ... ..	3,068
8.7 ... ..	8,786
16.6 ... ..	13,641
38.5 ... ..	16,702
266.5 ... ..	21,697

D. This sample contains 22 per cent. of nickel. It was not thoroughly tested, as the supply of CO<sub>2</sub> which happened to be available was insufficient. Its magnetic properties, however, were similar to the next sample.

E. The analysis of this sample was—

Fe.	Ni.	C.	Mn.	S.	P.	Si.
74.31	24.5	0.27	0.85	0.01	0.04	0.02 per cent.

As the material was given to me it was non-magnetisable at ordinary temperature; that is to say, the permeability was small, about 1.4, and the induction was precisely proportional to the magnetising force. The ring on being heated remained non-magnetisable up to 700° C. or 800° C. A block of the material did

not recalesce on being heated to a high temperature and being allowed to cool.

On being placed in a freezing mixture, the material became magnetic at a temperature a little below freezing point.

The material was next cooled to a temperature of about -51° C. by means of solid carbonic acid. After the temperature had returned to 13° C. the curve of magnetisation was ascertained; from this it appeared that the ring of the material which was previously non-magnetisable at 13° C. was now decidedly magnetisable at the same temperature. On heating the material it remained magnetisable until it reached a temperature of 580° C. At this temperature it became non-magnetisable, and, on cooling, remained non-magnetisable at the ordinary temperature of the room. The experiments showed that through a range of temperature from somewhat below freezing to 580° C. this material exists in two states, either being quite stable, the one being non-magnetisable, the other magnetisable. It changes from non-magnetisable to magnetisable if the temperature be reduced a little below freezing; the magnetisable state of the material does not change from magnetisable to non-magnetisable until the temperature is raised to 580° C.

The same kind of thing can be seen in a much less degree with ordinary steel. Over a small range this can exist in two states; but in changing its state from non-magnetisable to magnetisable a considerable amount of heat is liberated, which causes rise of temperature in the steel. It is observed in samples B and C of nickel steel, but at a higher temperature.

As might be expected, the other physical properties of this material change with its magnetic properties.

The wire as sent to me was magnetisable as tested by means of a magnet in the ordinary way. On heating it to a dull redness it became non-magnetisable, whether it was cooled slowly or exceedingly rapidly, by plunging it into cold water. A quantity of the wire was brought into the non-magnetisable state by heating it and allowing it to cool. The electric resistance of a portion of this wire, about 5 metres in length, was ascertained in terms of the temperature; it was first of all tried at the ordinary temperature, and then at temperatures up to 340° C. The wire was then cooled by means of solid carbonic acid. The wire was then allowed to return to the temperature of the room, and was subsequently heated; the heating was continued to a temperature of 680° C., and the metal was then allowed to cool. From this it appeared that in the two states of the metal (magnetisable and non-magnetisable) the resistances at ordinary temperatures are quite different. The specific resistance in the magnetisable condition is about 0.000052; in the non-magnetisable condition it is about 0.000072. The curve of resistance in terms of the temperature of the material in the magnetisable condition has a close resemblance to that of soft iron, excepting that the coefficient of variation is much smaller, as, indeed, one would expect in the case of an alloy; at 20° C. the coefficient is about 0.00132; just below 600° C. it is about 0.0040, and above 600° C. it has fallen to a value less than that which it had at 20° C. The change in electrical resistance effected by cooling is almost as remarkable as the change in the magnetic properties.

Samples of the wire were next tested in Prof. Kennedy's laboratory for mechanical strength. Five samples of the wire were taken which had been heated and were in the non-magnetisable state, and five which had been cooled and were in the magnetisable state. There was a marked difference in the hardness of these two samples; the non-magnetisable was extremely soft, and the magnetisable tolerably hard. Of the five non-magnetisable samples, the highest breaking stress was 50.52 tons per square inch, the lowest 48.75; the greatest extension was 33 per cent., the lowest 30 per cent. Of the magnetisable samples, the highest breaking stress was 88.12 tons per square inch, the lowest 85.76; the highest extension was 8.33, the lowest 6.70. The broken fragments, both of the wire which had originally been magnetisable and that which had been non-magnetisable, were now found to be magnetisable. If this material could be produced at a lower cost, these facts would have a very important bearing. As a mild steel, the non-magnetisable material is very fine, having so high a breaking stress for so great an elongation at rupture. Suppose it were used for any purpose for which a mild steel is suitable on account of this considerable elongation at rupture, if exposed to a sharp frost its properties would be completely changed—it would become essentially a hard steel, and it would remain a hard steel until it had actually been heated to a temperature of 600° C.

F. This sample contains 30 per cent. of nickel.

The remarkable feature in this case is the low temperature at which the change between magnetisable and non-magnetisable occurs, whether the temperature is rising or falling. Comparing it with the last sample, the character of the material with regard to magnetism is entirely changed.

G. The analysis of this sample is:—

Fe.	Ni.	C.	Mn.	S.	P.
66.19	33.0	0.28	0.50	0.01	0.02 per cent.

The remarkable feature of this material is the complete difference from the last but one, and the low temperature of change. There is but very little difference between the temperature of change when heated and when cooled.

H. The analysis of this sample is:—

Fe.	Ni.	C.	Mn.	S.	P.
26.50	73.0	0.18	0.30	0.01	0.01 per cent.

It is curious to remark that with this material the induction for considerable forces is greater than in the steel with 33 per cent. of nickel; and that it is greater than for a mechanical mixture of

\* Abstract from Proceedings of the Royal Society.

iron and nickel in the proportions of the analysis, however the particles might be arranged in relation to each other.

The critical temperature of the material is 600° C.; it shows no material difference between the critical temperatures for increasing and diminishing temperatures.

LIFE AND EFFICIENCY OF ARC LIGHT CARBONS.\*

SINCE the earlier stages of arc lighting little or no increase in the efficiency of the carbon points appears to have been made. Now that the dynamo machines and lamps have reached such a state of perfection, the subject presents itself as pre-eminently important. The arc light pencil, considered as an individual part of the system, is indeed a small thing, but in it undoubtedly lies the weak spot of the system. With a view of studying the action of modern carbon pencils, the investigations herein described were undertaken. The carbons experimented upon were all of American manufacture, and were procured from five companies (A, B, C, D, E).

While the greater part of the research was upon the life and efficiency of the pencils, observations were also made in other directions.

The subject was treated under the following heads:—

- 1. Structure of the carbons.
- 2. Life tests.
- 3. Efficiencies.
- 4. Candle-power measurements.
- 5. Observations of the arc and carbon points.

1.—STRUCTURE OF THE CARBONS.

It is well known that the life and efficiency of a carbon depends upon the system in which the carbon is burned. For instance, the requirements of the low tension system seems to be a carbon that is hard, well plated and a good conductor, the latter being the most important. In the high tension system, on the contrary, hardness and conductivity seem to be of secondary importance. There is a tendency to "flame" and burn unsteadily when a hard carbon is used in this system, and a softer one sometimes becomes necessary.

It is interesting to note the methods employed by carbon manufacturers to attain the conditions above mentioned. In one of the largest carbon works, "forced" carbons, or those made by "squirting" the plastic material through a die, are manufactured for both high and low tension systems of lighting, to the exclusion of moulded pencils. On the other hand, another company makes no forced carbons, but claims that its moulded carbons are superior for either system. The classification given below shows the types of carbons now upon the markets for both systems.

Thin transverse sections of all the specimens were cut and mounted on glass slides, and a microscopical examination made.

Carbon.	High ten-sion.	Low tension.
A	(1) moulded	(2) forced
B	(3) "	(4) moulded
C	(5) "	(6) "
D	(7), (8) forced	(8), (9) forced
E	{ (10) moulded } { (11) forced }	(12) "

On examination a marked difference is seen between the structure of a moulded and a forced carbon. In the high tension pencil (1) the structure is a loose one, while the low tension rod (2) is marked by a dense and homogeneous structure; the size of the grains of carbon in the latter case is much less than in the former, and the particles have a more metalloid lustre. There is probably considerable air space in (1). The two rods thus have respectively the qualifications stated above required for high and low tension pencils. The resistance of (1) was found to be 199 ohm; (2) 144 ohm; while (2) plated was 084 ohm.

In class B, (3) and (4) were of similar structure, and the resistance was varied by the thickness of the copper plating.

In class C (5) and (6), both moulded carbons, the structure varies owing to a far higher pressure being employed in moulding the low tension rods.

In group D, besides a difference in pressure during manufacture, there is also a difference in the "mix" or composition of the carbon; (8) is an attempt to construct a carbon suitable for either high or low tension and is a mean between (7) and (9).

In group E, there is great dissimilarity between (10) and (11) although used for the same purpose; (11) being very similar in structure to (9) D, but containing less pure carbon. The efficiency of these types will be discussed further on.

2.—LIFE TESTS.

If a carbon is burned with a small current its life will be long, at a sacrifice of light-giving properties. If, on the other hand, a

\* Abstract of paper read by Louis B. Marks before the American Institute of Electrical Engineers, Boston.

large current is used, there may be a gain in efficiency at a sacrifice of life. The question arises—what is the proper current to use. Of course circumstances determine to a large extent the answer, and generally such a current is used as gives a fair mortality at a reasonable efficiency of the carbon.

The high tension carbons submitted for test were designed to be burned at about 10 ampères, and the low tension at about 20 ampères. In the life tests a Thomson lamp was used for the high tension runs, current being constantly kept at 10 ampères and P.D. at 50 volts. For low tension carbons a Weston lamp was used. The pencils were accurately weighed before and after the runs, and the life calculated on the assumption that the carbons were homogeneous. Each set of pencils were burned an hour. It has been stated that "with carbons of the same hardness and length, but having different diameters, the larger will undoubtedly outlive the smaller. Of carbons of the same diameter and length, but differing in hardness, the harder will outlive the softer." This statement presupposes that the conductivity of the carbon is directly dependent on the hardness or softness of the pencil. In order to examine more fully the relation between diameter, resistance and mortality of a pencil, six sets of carbons of the brand B, varying in diameter from  $\frac{1}{8}$  to  $1\frac{1}{8}$  inches were carefully weighed, their resistances measured by the Wheatstone bridge method, and the pencils burned with a constant current of 10 ampères, the P.D. at the terminals of the lamp being kept at 50 volts. The diameters and resistances respectively of the upper and lower carbons were in each case practically the same. A mean of 10 micrometer measurements of the diameter was taken as correct. The duration of each run was 60 minutes.

From the results obtained it appears that the life of a carbon varies directly with its diameter and inversely with its resistance. This law holds good only for homogeneous carbons of the same manufacture, type, and structure, and as stated previously, for constant current and voltage.

Taking the  $\frac{1}{8}$  inch (.505 inch) and 1 inch (.986 inch) pencils as standards and from the relation above stated, calculate the mortality of the other carbons.

The table gives a comparison between the actual and the calculated life of the specimens tested.

TABLE.				
Carbon.	Mean diameter in inches.	Standard $\frac{1}{8}$ inch (.505)	Standard 1 inch.	Actual life hours.
		Calculated life hours.	Calculated life hours.	
B moulded light	.453	10.92	9.32	10.64
" "	.618	15.10	13.62	13.64
" "	.739	21.58	19.44	21.38
" "	1.195	36.40	33.04	33.49

Thus it appears that the calculated life is larger than the actual when the half-inch carbon is taken as a standard, and smaller when the 1 inch pencil is made the basis of calculation. Every precaution is taken to avoid discrepancies, but errors are apt to creep into the work. The results, however, without doubt, point to the existence of such a law as has been quoted.

Next, experiments were made to determine the curve for current and mortality of the pencil, when the voltage is kept constant. The range of current was from 6 to 13 ampères, and greatest variation in tension was one volt.

Another series of tests was made with constant currents and varying voltage. The current being kept at 10 ampères, and the range in tension was from 40 to 60 volts. In these tests the consumption of carbon was taken for both pencils + and -.

Very little has been published relative to the life of the plus and minus carbons; Munro and Jamieson state that, "with continuous currents the plus wastes twice as fast as the minus carbons. With alternating currents the upper wastes 8 per cent. faster than the lower if the carbons are vertical, but at the same rate if horizontal." The accompanying table shows the result of our tests on this point.

TABLE.—RELATIVE LIFE OF THE PLUS AND MINUS CARBONS

Carbon.	Current in amperes.	E.M.F. volts.	Time of run in mins.	Loss + grms.	Loss - grms.	Life $\frac{1 \text{ in.}}{1 \text{ in.}}$ +
B moulded high ten.	10	50	60	5.28	4.40	1.20
B " low ten.	10	50	60	5.14	3.27	1.57
A " high ten.	10	50	60	5.98	3.20	1.87
E forced low ten.	22 $\frac{1}{2}$	28	150	193.18	74.42	2.59
B molded low ten.	22 $\frac{1}{2}$	28	150	166.60	51.50	3.23
C " " "	22 $\frac{1}{2}$	28	145	151.00	41.00	3.68

From this table it can be seen that the + and - carbons may burn away fairly in equal proportions, or may waste in the plus carbon more than three and a half times as quickly as the minus carbon.

For determining the influence of diameter and resistance upon the relative life of the plus and minus carbons, a number of

moulded high tension carbons, A brand, were used, taken from the same batch, and burned with a current of 10 amperes and a voltage of 50. The experiments seem to show that  $\left\{ \frac{\text{life} -}{\text{life} +} \right\}$  appears to become greater with increase of diameter of carbon; but probably the inequality in the diameters of the + and - pencils respectively, as well as the difference of resistance of the two carbons of a set, explains the increase in the ratio. For assuming that under the conditions the life of a carbon varies directly with its diameter and inversely as its resistance, this is an indication that if the diameters and resistances respectively of the + and - carbons were the same in each run, the ratio would be practically the same for all sizes of carbons.

The experiment with change of current and constant potential shows that the change of current, other things being constant, produces very little effect on the ratio  $\left\{ \frac{\text{life} -}{\text{life} +} \right\}$ .

On the other hand, when potential differs and current is constant, the higher the potential the nearer the approach to unity is obtained in the ratio.

The relative life of carbons of the same diameter is influenced chiefly by the difference in the resistance of the carbons and the variations of the P.D.

It was conjectured that blowing the arc during a run with a magnet would increase the life of the + carbon; the reverse was found to be the case, but with little effect on the - carbon.

#### EFFICIENCY.

Two methods of determining the efficiency of each set of pencils were employed. The first was the method used by Mr. Merritt in obtaining the efficiency of the incandescent lamp, and subsequently by Mr. Nakano in his work on the efficiency of the arc lamp. By this method the deflection of a galvanometer was taken as a measure of the energy of the total radiation falling upon the face of a thermopile, the dark leads being cut off by passing the rays through an alum cell. The second method dealt with candle-powers obtained by photometric measurements. Mechanism was employed whereby the angle of radiation from the arc could be altered without altering the distance of the centre of the arc from the thermopile. In the results it was noticed that the horizontal efficiency is very small compared with the maximum; that relatively high efficiency in a forced high tension carbon is obtained only at the expense of life; that a moulded carbon is, generally speaking, superior to a forced for high tension and vice versa for low tension. In the case of the high tension carbons of brand B and D, of smaller diameter than that of the other pencils, we have a relatively higher efficiency, it was shown last year that the efficiency varies inversely as the diameter. A copper-plated carbon lasts longer than a naked one, but the mean sphericity appears to be the same for both, or but very slightly in favour of the coated carbon. The use of the plating prevents disintegration, and so prolongs the life of the pencil; the actual amount of combustion is apparently the same in either case.

The conclusions drawn from the series of candle-power tests show that the efficiency of low tension carbons, and especially of

Spherical C.P. =  $\frac{1}{2}$  horizontal C.P. +  $\frac{1}{2}$  maximum C.P. The average error is only about 5 per cent., and is most generally correct as an approximation. For the total radiation where the efficiency depends upon the ratio  $\left\{ \frac{\text{luminous radiation}}{\text{total radiation}} \right\}$  Gérard's law does not hold, but for approximations spherical efficiency =  $\frac{1}{2}$  horizontal +  $\frac{1}{2}$  maximum.

#### OBSERVATIONS OF THE ARC AND THE CARBON POINTS.

With a given potential difference between the terminals of the lamp, the length of the arc depends upon the current flowing, and increased as the current becomes greater. If the current be constant, the length of arc increases with the P.D. Examining the carbons after burning at varying currents and constant P.D., it was seen that with 5 amperes there was a tendency to form a "mushroom" on the lower or negative carbon; the latter is eaten away considerably just below the tip. With 10 amperes it is less, and at 15 amperes hardly perceptible. The plus carbon has a variable diameter of crater, increasing with the strength of the current, but with a greater depth with the lower currents. With high currents the carbon is disintegrated to a greater distance above the points than with low. With constant current and increasing potential, the shape of the carbons change from a point at 40 volts to a blunt end at 60 volts. The mushroom that forms where the carbon is burned with low current and high voltage, is absent at high current and low voltage. At 60 volts the crater had disappeared, and the carbons flamed; below a certain voltage for every make of carbon there is a point when hissing commences.

At too high a voltage the crater breaks away and flaming begins. Soft cored carbons somewhat remedy this defect and should not flame at all at the proper voltage for the particular make. The breaking off of the small mushroom button on the negative carbons is invariably accompanied by hissing.

The remedy for irregularities in the burning of arc lamps lies with the carbon manufacturer.

In the present state of the art of carbon manufacture, a careful discrimination in selecting carbons should be urged on all central station managers; as recently a comparative test of the best known carbons in the market carried out by Mr. G. F. Peck, of Brooklyn, resulted in a saving of 64.73 electrical horse-power in a station burning a thousand lamps.

## PROCEEDINGS OF SOCIETIES.

### The Institution of Electrical Engineers.

"The Working Efficiency of Secondary Cells." By W. E. AYRTON; C. G. LAMB, E. W. SMITH and M. W. WOODS, Associates. Read at Edinburgh, Wednesday, July 16th.

(Concluded from page 140.)

These two conditions, however, we have fulfilled by the employment of the following device, by means of which the difference between the values of  $v$  and of  $\epsilon$  was measured to the one-thousandth

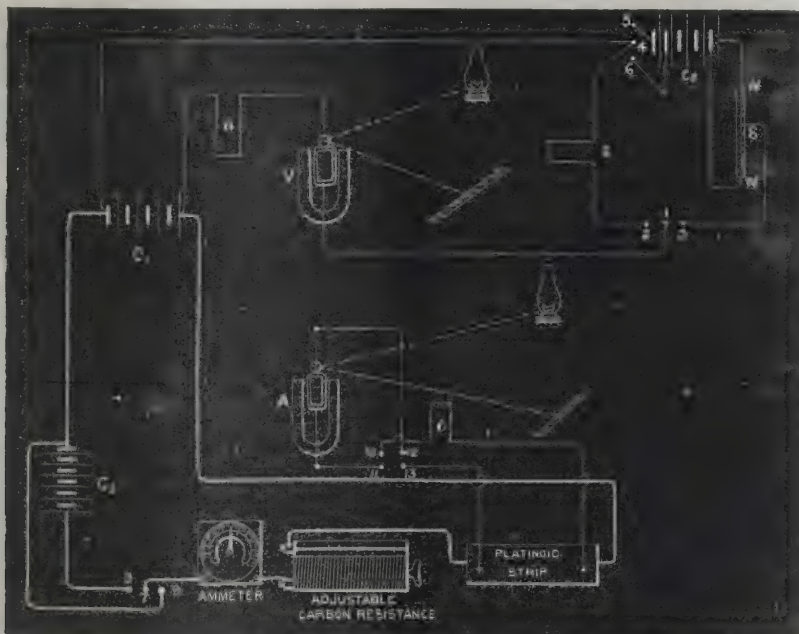

FIG. 10.—APPARATUS FOR MEASURING THE RESISTANCE OF THE ACCUMULATORS  $C_1$ .

moulded low tension carbons, is comparatively small; while the efficiencies of moulded high tension carbons are as high as 783 to 840 candles per electric horse-power expended in the lamp; low tension pencils of the same diameter nearly give only 594 to 502 candles per electric horse-power.

M. Gérard's formula, for the mean spherical candle-power of a lamp, is of sufficient exactitude for practical purpose.

of a volt at identically the same moment that the values of  $v$  and  $\epsilon$  were measured. The process was as follows:—

1. The sensibility of the voltmeter was adjusted so that 12 volts produced a deflection of 600 divisions, and  $v$ , the P.D. at the terminals of the four accumulators under test, was measured.

2. A compensating E.M.F. was introduced into the circuit just sufficient to bring the spot of light to zero.

3. The sensibility of the voltmeter was increased 60 times.

4. The main circuit was broken, and the time variation of  $\epsilon$ , the E.M.F. of the accumulators under test, observed by noting the position of the spot of light at the successive ticks of a metronome, whose rate of going was before each experiment carefully adjusted by comparing the metronome with a chronometer.

5. A time curve for the values of  $\epsilon$  was drawn, and by producing it back until it cut the line passing through time nought—that is, the time when the main circuit was broken—we obtained the value of  $\epsilon$  at the same moment that the values of  $v$  and  $a$  were measured.

The apparatus employed is symbolically shown in fig. 10.  $c_1$  are the four accumulators under test; when they were being charged by means of the accumulators  $c_2$ , a bridge-piece was placed so as to join the mercury cups 7 and 8; whereas, when  $c_1$  were being discharged, mercury cup 7 was joined to 9 instead of to 8. In both cases the current passing along the thick lines through an A. and P. magnifying spring ammeter, whose indications furnished an approximate measure of the current, through an adjustable carbon resistance and a platinoid strip which could carry the maximum current, 10 amperes, used in these tests, without its resistance being perceptibly altered. To two points of this strip were soldered two wires going to the mercury cups 10 and 13; these were joined respectively to 11 and 12 in charging, and to 12 and 11 in discharging, so that the current always went through the D'Arsonval galvanometer, A, in the same direction. This galvanometer then measured the charging or discharging current, its sensibility being such that for a current of 9 amperes passing through the circuit a deflection of 600 scale divisions was produced when the resistance in  $d$  was 185 ohms, that of the galvanometer A itself being 52 ohms.

By joining the mercury cups 1 and 2 with a bridge-piece, the P.D. between the terminals of the accumulators under test,  $c_1$ , could be measured with the voltmeter,  $v$ ; the sensibility being such that with a resistance of 791 ohms in  $a$ , and 63,696 ohms in  $b$ , a deflection of 600 scale divisions corresponded with a P.D. of 12 volts. By connecting the mercury cup 1 with 3 instead of with 2, the resistance,  $b$ , was cut out of the circuit, and the sensibility of the voltmeter,  $v$ , was increased 60 times. If now 4 were connected with 5 or with 6, and the sliding contact,  $s$ , moved along the thick wire,  $w$ , a point could be found such that no current passed through the voltmeter,  $v$ . Next, the main circuit indicated by the thick wires was broken, when the spot of light would move quickly across a portion of the scale, and then continue moving right across the rest of the scale. The first part of this motion was of course due to the sudden variation of the P.D. at the terminals of the accumulators,  $c_1$ , on the current through them being stopped, while the continuation of the motion was due to the subsequent variation of the E.M.F. of these accumulators after the current was stopped. And the value of the E.M.F. at any moment was equal to

$$v \pm \frac{0.2 d}{600},$$

where  $d$  was the deflection of the voltmeter spot of light at the moment in question, and  $v$  was the P.D. between the terminals of the cells,  $c_1$ , just before the main circuit was broken, and which was measured by the voltmeter deflection when mercury cup 1 was connected with 2. In discharging the + sign was, of course, used, and in charging the - sign.

This P.D. at the terminals of the four accumulators under test,  $c_1$ , and which had to be balanced by the E.M.F. of the accumulators,  $c_2$ , approached 9.6 volts towards the end of a charge, while it fell to 7.6 volts at the end of a discharge. In the former case the E.M.F. of four cells and a portion of the fifth of the compensating accumulators,  $c_2$ , was employed, while in the latter the E.M.F. of three and a portion of the fourth sufficed. Hence, during the charge mercury cups 4 and 5 were connected together, while during the discharge it was 4 and 6 that were connected together. The portion of the E.M.F. of the last of the compensating cells was, as shown in the figure, obtained by shunting this cell through a platinoid wire,  $w$ , of about 2 ohms resistance, and making contact with a point of this wire farther from, or nearer to, the positive pole of this cell. This adjustment of the position of  $s$  caused very little change in the resistance of the voltmeter circuit, because the resistance of  $w$ , was but a small portion of the entire resistance in the voltmeter circuit.

This method of measuring the resistance of accumulators was applied by three of the students of the Central Institution—Messrs. Müller, Stephens, and Wightman—to determine the variation of the resistance during the entire discharge of the cells with 10 amperes, and charge with 9; further, during May and June of this year Mr. Müller has, with great perseverance, been making an uninterrupted series of observations, day and night, to determine the resistance during the entire discharge and charge for various currents. For each of these currents the cells are being brought to a steady working state by many discharges and charges being successively and without interruption made with each current. In the case of the small current the time of a charge and discharge is tediously long, the charge, for example, with 3 amperes requiring 40 hours to raise the P.D. from 1.9 to 2.4 volts per cell, so that several weeks have to be spent obtaining the resistance for this current. This investigation of resistance is not yet completed, and therefore we do not propose in this paper to refer to the variation of the resistance of a cell with different currents when the cell is brought to a steady working state for each current. Such an experiment has not, as far as we are aware, ever before been attempted with accumulators

former observers having contented themselves with merely observing the variation of the resistance when the current during discharge or charge was abruptly changed from one value to another. This is a very different thing from ascertaining how the resistance of an accumulator varies with the current when each of the different currents employed is steadily used for some weeks in the discharging and charging of the cell, until the cell has arrived at a steady working state for the current in question.

We give in fig. 11 an example of the time fall of the E.M.F. on breaking the circuit for eight periods of 20 seconds during the charge. The curves are all drawn to the same scale, but, in order to get the curves into a reasonable space, a different zero line has been employed in drawing each curve. The actual E.M.F. in volts per cell is given for several points on each curve, so that the time rise at any period of the charge can be easily seen. The E.M.F. at the moment of breaking the circuit in each case is, as already explained, obtained by seeing at what point the curve cuts the vertical line through the time 0. The value of this point in volts is, in fact, what an infinitely dead-beat voltmeter would indicate immediately after the circuit was broken.

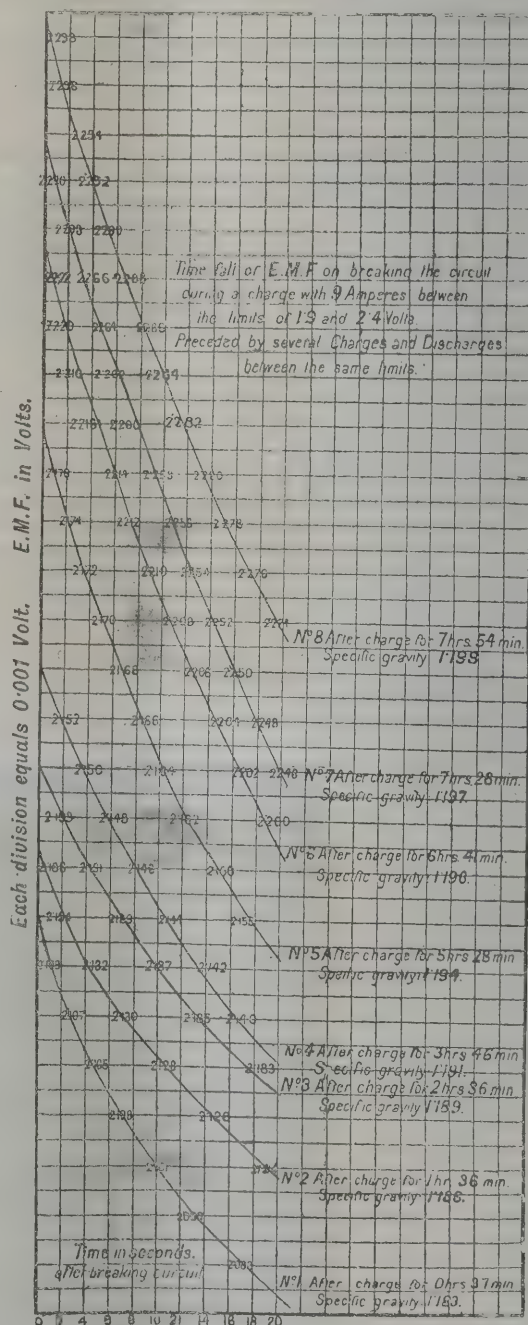

FIG. 11.

It will be observed that the time fall of E.M.F. on breaking the circuit becomes more and more rapid as the charge continues.

The top curve in fig. 12 gives the P.D. at the terminals of one accumulator, charging with 9 amperes; while the second curve gives the simultaneous values of the E.M.F., being, in fact, the curve drawn through points whose abscissæ are the times—0 hours 37 min., 1 hour 36 min., &c.—for which the eight curves on fig. 11 are drawn, and whose ordinates are the values of the points where these curves cut the vertical line drawn through the zero of time in fig. 11, or time when the charging circuit was broken. The lowest curve on fig. 12 gives the resistance of the cell at any

moment during the entire charge with 9 ampères, the ordinates of this curve being calculated from the formula

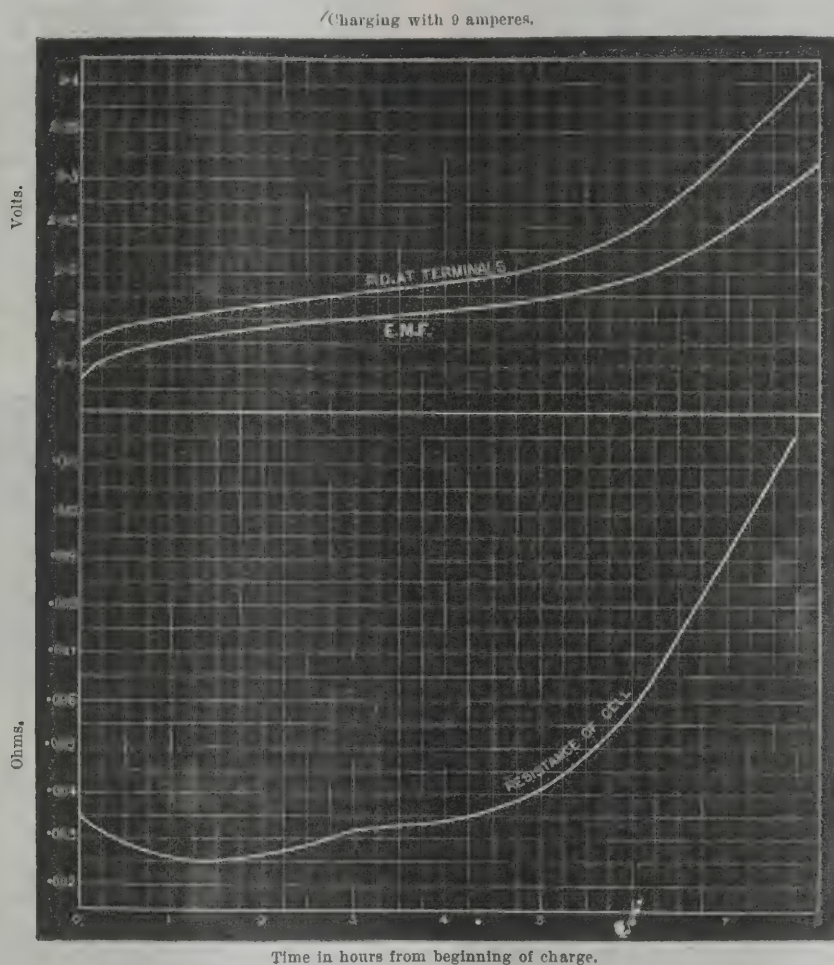

$$\frac{V - E}{9},$$

where  $v$  and  $E$  are values of the P.D. and the E.M.F. of the cell at the same instant.

As the charging proceeds the resistance of the accumulator at first falls, and reaches a minimum; it then increases, at first

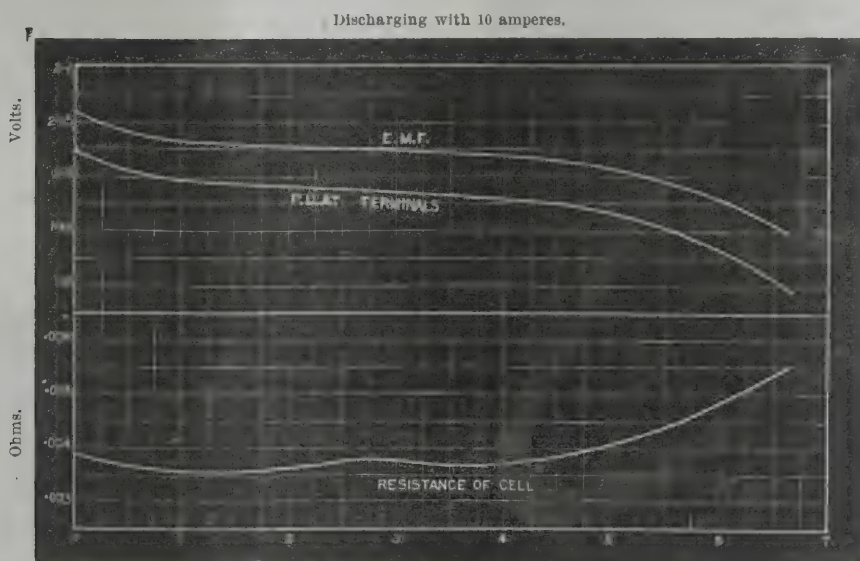

density allowed—viz., 3.787 ampères per square foot—is about 0.11 ohm per square foot of positive plate.

Fig. 13 gives the P.D. at the terminals of one of the cells during the whole of a discharge with 10 ampères, the simultaneous values of the E.M.F. and of the resistance. The resistance at the commencement of the discharge is a little higher than at the commencement of the charge, and the minimum value to which it diminishes is not as low as the minimum attained by the resistance in charging. At the end of the fifth hour of discharge

Time in hours from beginning of charge.

FIG. 12.

Time in hours from beginning of discharge.

FIG. 13.

slowly, but as the charging approaches the finish the resistance rises very rapidly, so that when the P.D. per cell is 2.4 volts the resistance is five times as great as its minimum value, which is reached shortly after the commencement of the charging. Taking 0.045 ohm as the average resistance during charging, and remembering that there are in these cells two positive plates each surface of which is  $9\frac{1}{4}$  into  $9\frac{1}{4}$  inches, and that all four surfaces are equally active, it follows that the mean resistance of the 1888 E.P.S. type of cell while charging with the maximum current-

and charge the resistance is practically the same. After that however, there is a marked difference: the resistance in discharging does not rise as rapidly as in charging; and hence, since, in addition, the time of a discharge is necessarily less than of a charge, the resistance never reaches as high a value in discharging as in charging.

If we take 0.038 ohm as the mean resistance during a discharge with 10 ampères, then it follows that the mean resistance of the 1888 E.P.S. type of cell while discharging with the maximum

current-density allowed—viz., 4.208 ampères per square foot—is about 0.09 ohm per square foot of positive plate.

Both in charging and in discharging with constant currents, the greater part of the time variation of the P.D. at the terminals of an accumulator is due to an actual variation in the E.M.F. itself; and it is only towards the end of the charge and of the discharge, when the resistance of the cell becomes relatively large, that the slope of the P.D. curve becomes practically different from that of the E.M.F. curve.

We may mention, in conclusion, that the results which we have obtained with accumulators made to go for long periods through definite cycles in charging and discharging, have been so interesting that we are now engaged on the design of an apparatus which will automatically keep the current constant for any time at any pre-arranged value, which will automatically change over from charge to discharge, or from discharge to charge, when the P.D. per cell reaches any pre-arranged limit, and which will record the P.D. at the terminals of the cell, and also its E.M.F. during the whole period.

We hope, therefore, at some future period to be able to present a graphical record of the life-history of accumulators from their first formation to their death.

"On Some Experiments in Radiometry."\* Paper read by A. R. BENNETT, Member.

In the course of some experiments with radiometers, the author has been able to detect effects which are of interest, and which, if observed before, have not been published, so far as he is aware.

Some of the experiments detailed may not bear any apparent relation to electricity; but the fact that electrical vibrations and those which give rise to heat and light, are now admitted to be but different phases of the same phenomenon, must be the author's excuse for troubling the Institution with them.

Rotations of the vanes of ordinary radiometers can readily be produced by electricity.

An unusually sensitive radiometer placed between the poles of an influence machine (fig. 1) has its vanes strongly affected. As a rule, oscillation to and fro only is set up, but this may readily be converted into rotation by timing the impulses from the machine to the swinging of the vane, or by giving the vane an initial start by lighting a match, or jerking it. Then rotation continues so long as the machine is worked. Generally, but not invariably, the motion, if not started mechanically in the reverse, is in the same direction as would be produced by heat. After the machine stops, the vane continues to rotate for a time, even after the knobs of the machine are brought together; and when it is stopped, a single impulse is sufficient to set it off again. In the dark the bulb appears filled with the usual phosphorescent light.

The effect appears at least partly electroscopic, since, on starting, the nearest vane is usually attracted toward, and then repelled from, the knob.

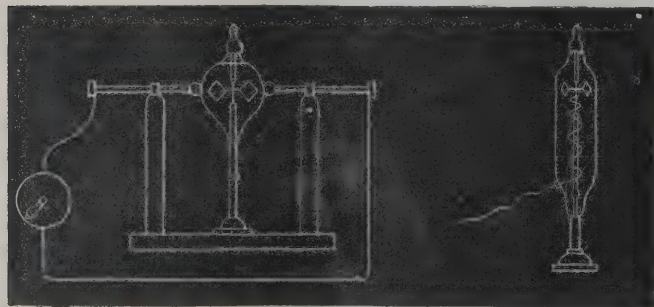

FIG. 1.

FIG. 2.

Placed against one pole only of the machine the vane oscillates feebly, but can be nursed into rotation.

With radiometers of special make more marked effects can be obtained. Several instruments having vanes fitted with metal caps, working on pivots connected to the outer air by wires fused in the glass were prepared (fig. 2).

Such radiometers really form condensers or Leyden jars, having the inner coating—the vane—free to move. The dielectric is the rarefied air, and the glass the outer coating.

When the vane is connected to one pole of an influence machine, it rotates until the condenser, of which it forms a part, is fully charged, and then stops; when the current is arrested, the vane rotates again in the same direction, until the greater part of the charge has been lost. So, by timing the impulses from the machine, continuous rotation can be produced. In the four-vaned instrument on the table the motion produced is in the reverse direction to that due to heat, the black being seemingly attracted; but in that instrument the vanes are bent at an angle which would naturally render the impulses effective in the direction indicated. In the two-vaned instrument also shown the vanes have no bias, and the motion is sometimes in the one direction and sometimes in the other. This charge and discharge effect is

produced feebly when the instrument is standing in the air, the vane only being connected to the machine. When the glass is brought near to or touches the opposite pole, it becomes more pronounced; and when the glass is coated with tinfoil and put in contact with the opposite pole, it becomes strong and invariable. If the foil is removed out of actual contact, but retained within free sparking distance, the vane no longer has periodic dead points, but discharges constantly to the outer coating, and rotation continues so long as the machine is worked. The process may be reversed by connecting one pole to the foil, and drawing the sparks from the vane by means of its connecting wire. The direction of rotation continues, however, as before. If the end of the vane wire be of small gauge—No. 40, for instance—it vibrates violently while discharging and with such rapidity that it seems double-ended, two perfect, and, apparently motionless, images of the ends appearing half an inch or more apart.

Continuous rotation may likewise be attained by means of an automatic discharger consisting of a strip of foil hanging from the outer coating of the radiometer opposite a contact point, which may be earthed or connected to opposite pole of machine (fig. 3). The foil diverges from the glass when the condenser gets charged up, and, making contact with the point, is discharged and falls back, only to be again repelled. (Experiment shown.) By this means the condenser is automatically prevented from becoming full, and the vane rotates so long as it is supplied with electricity from the machine. Conversely, the foil may be charged and the make-and-break performed by means of a light wire attached to the vane connection.

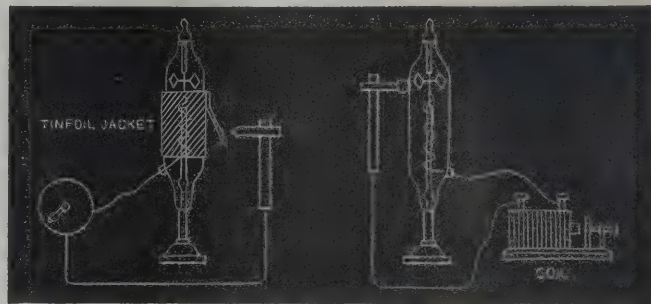

FIG. 3.

FIG. 4.

The radiometer with only one arm and two vanes is extremely sensitive, and exhibits the foregoing condenser effects in a marked degree. While charging or discharging it revolves with such rapidity as to make the arm appear a circle; and when fitted with an automatic discharger, each secondary discharge after the main one has been effected is accentuated by a kick. The rotation in this case is right and left indifferently, apparently according to the direction in which it first obtains an impulse. (Experiments with this instrument were shown after the paper.)

Experiments were made with these radiometers with the current from a Ruhmkorff coil.

Placed between points or knobs connected to the secondary of the coil, an ordinary radiometer could be got to rotate if an initial jerk were given, either to left or right. Left to itself, it oscillated only, the tips of the vanes being alternately attracted towards the knob and repelled from it.

With a special radiometer connected as in fig. 4, oscillation only could be got with dry glass; but on wetting the circumference of the tube round the vane, rotation was immediately set up in the reverse direction to that caused by heat, and continued until the glass dried. Merely breathing on the glass caused rotation to recommence. The effect cannot be wholly due to the fact that the moisture made a conducting ring round the glass, as a band of tinfoil had no result unless wetted on the outside, when very feeble rotation began.

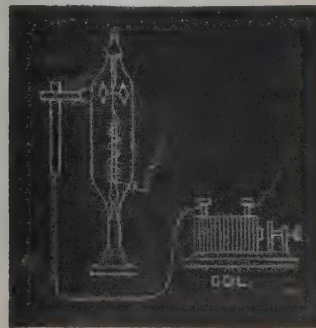

FIG. 5.

Rotation also occurred with wetted glass with connections as in fig. 5, the vane and one end of the coil being insulated.

In these induction coil experiments the silver side of the vane seemed uniformly repelled and the black attracted.

All the foregoing experiments exhibit beautiful luminous effects when viewed in the dark. Streams of phosphorescent light pass

\* Paper read at the special meeting of the Institution of Electrical Engineers at the Edinburgh International Exhibition, July 17th, 1890.

between the vanes, especially their edges, and the glass. The two-vaned instrument may be made to rotate by connecting one terminal of the coil to the vane and holding the other in one hand; two fingers (wetted) of the other hand being placed on opposite sides of the glass, rather under the level of the vane. The formation and disappearance of the lines of force between the wet finger tips and the edges of the vanes as they alternately approach and recede, then become vividly apparent.

Radiometers of this construction being really Leyden jars, a good deal depends on the glass of which the instruments are made. A radiometer made of a different glass from those now before you exhibited rotation freely with coil when dry, although wetting increased the effect. With that instrument an air-space of one-eighth of an inch could be interposed between the knob and the glass without stopping the movement; and making the connection with the glass by means of a wetted finger quickened the rotation.

But the author, wishing to discover how far the effects were due to the rarefied air, broke the glass. It was found that the movements continued for a time after air was admitted, but ceased as soon as the inside of the tube became damp.

But the moment the tube was broken it became apparent that the vane was subject to new influences, and was even more sensitive in responding to them than it had been to heat or electricity whilst still in its prison of rarefied air.

Poised in the open air, it became an indicator of the utmost delicacy of air currents set up or altered in direction by the approach or movement of heated bodies. When placed in a quiet room, free from draughts, the movement of the person from one place to another, however slowly and carefully it might be managed, was sufficient to set the vane in motion. The approach of the body close to the vane—softly, so as to avoid the mechanical creation of draught—would agitate it powerfully, and frequently rotation for several seconds would be set up.

Experiments were tried with vanes of various substances, with and without lamp-black, but the rotation seems altogether independent of the character of the vane. Anything very light will do, and paper does as well as talc or aluminium.

When the light of the sun or of a lamp, or the heat of a kettle is made to fall on one side of the vane only, continuous rotation towards the light or heat is set up. In a dark room, without a fire, the light from a lamp was made to shine through a funnel of small diameter (fig. 6), so that one side of one of the fans only was illuminated at the time. After some hesitation and preliminary oscillation the fan invariably advanced towards the light, and continued to rotate in that direction so long as the persons in the room kept 12 or 14 feet away, remained quiet, and refrained from changing their positions. The movement of a person only 3 or 4 feet, however cautiously, would cause the vane to hesitate and stop for a moment or two, and the crossing of the room always violently disturbed the vane, sometimes causing the rotation to

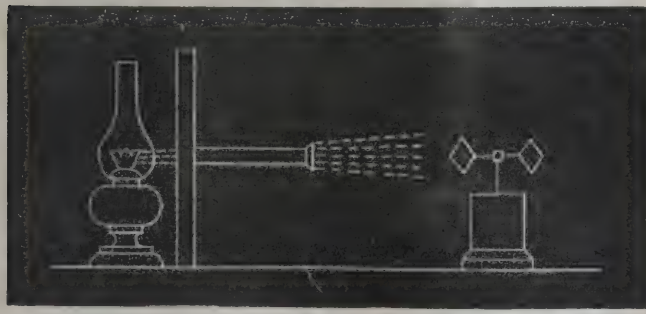

FIG. 6.

be reversed for a time. But when the body was kept stationary in its new position the old rotation toward the light recommenced, and continued until again disturbed.

This, and the facts that rotation is set up, and motion already existing is arrested, by the mere proximity of the person, seem to indicate that every living body and every object of a temperature higher than the surrounding air constitutes a field of force. It heats and rarefies the air around it, which ascends under pressure of the heavier and colder outer air. Every person not in the vicinity of bodies as warm, or warmer than himself, is a centre towards which air is always advancing from all directions, and on every plane from his feet to his head. On reaching him it is heated and ascends, so that he is surrounded by a column of air, warmer and lighter than the general mass, and always in motion upwards. The light and delicately balanced vane is sensitive enough to reveal the presence of the resulting horizontal air currents. This is probably the explanation of the experiment shown in fig. 6. The side of the fan facing the lamp, radiating the heat it receives, rarefies the air in front of it, which ascending, the fan is forced forward by the greater pressure of the colder air behind it. Each fan in turn, as it comes under the ray of heat, is subjected to the same influence, and so rotation is attained towards the lamp.

The movement of a body from one part of the room to another changes the direction of the air currents in the room, and creates eddies and whirls which disturb the vane for a time. If the body is placed behind the vane, or close beside it, it neutralises or reverses the influence of the heat ray from the lamp, and stops rotation. So the further away the observer places himself the better for the experiment.

The motion of the air toward the body can be shown by two vanes partially screened from the body, and wholly from each other, as in fig. 7. The outer fans of each vane will advance toward the observer, and the two vanes will consequently rotate in different directions under the influence of cold air advancing towards the body. It is curious that the first movement of the vanes in presence of a ray of heat indicates repulsion.

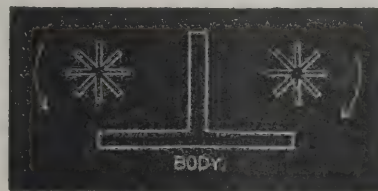

FIG. 7.

It occurred to the author that a complete circle of light material should show the currents as well as a vane, and on making a cap of tissue paper and balancing it on a needle point, it proved to be so. The cap is, under some circumstances, more delicate than the vane, and more sensitive to heat than the most sensitive Crookes's radiometer that could be procured. It was found that when a vane or a light paper cap was placed within a circular screen not quite closed (fig. 8), a ray of heat suffered to fall on the screen near the

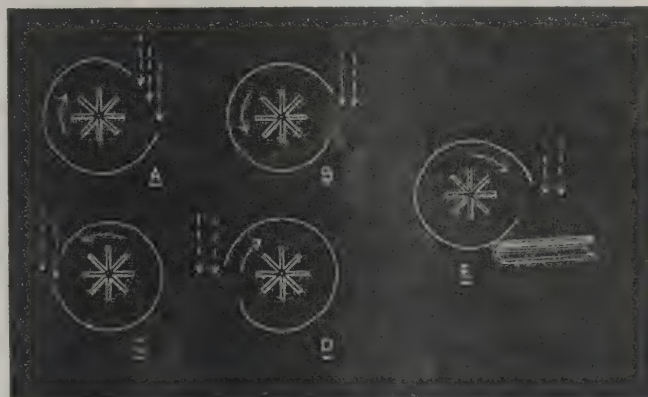

FIG. 8.

opening would set up air currents and rotation of the vane or cap, which would continue as long as the heat was applied. The direction of rotation depends on the form of the aperture in the screen. When opened out, as in A, fig. 8, so that the heat indicated by the dotted arrows falls partially within the screen, the vane or cap is repelled from the source of heat; when, as in B, the ray falls on the back of the opening, it is attracted. The direction of rotation may thus be changed by adding to the screen; when, as in C, the vane is being attracted, the placing of a book or other object, as in E, immediately causes it to stop and reverse.

This arrangement is of extreme sensitiveness. If the observer keeps well away, rotation will continue after sunset and under a cloudy sky, when the opening of the screen is exposed to the window. It excels in this respect a Crookes's radiometer of ordinary make, which on several occasions was noticed to give up work before the screened paper cap. Simultaneous rotation of two

FIG. 9.

FIG. 11.

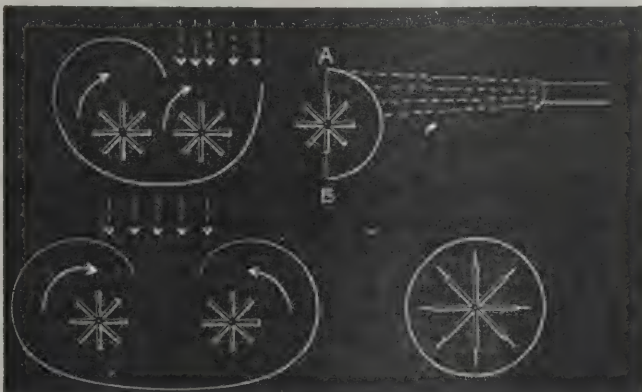

FIG. 10.

FIG. 12.

vanes or caps in the same (fig. 9) or in different (fig. 10) directions may be secured with one screen.

The movements of neighbouring bodies are not of so much importance as with unscreened vanes, as except in the direction of the opening exterior influences, unless very violent, are inter-

cepted. Placing the body across or near the opening disturbs, and will even stop, rotation.

Rotation may be set up by applying heat to the exterior of the screen. Thus, a ray of heat falling at A or B (fig. 11) causes rotation.

Vanes or paper caps, protected from the outer air by glass clock-shades, will rotate under sunshine or other source of heat, direction being determined by position in respect to wall of shade.

Rotation is produced by placing a heated screen round a vane. Thus, if a tinned iron screen be taken and heated, either uniformly or at one or more points, it will when placed over a vane immediately set up rotation which will continue, even in the dark, until the screen has cooled to the temperature of the air.

Similarly, a vane inside a screen of good conducting material, as metal, will rotate when heat is applied to one point of the exterior of the screen. This can be shown by applying the tip of a hot poker to the outside of a tinned iron screen.

Although rotation occurs best in screens having an opening to the outer air, it will take place when no such opening occurs, as in fig. 12. Thus, a vane inside a metal cylinder will oscillate and then rotate when heat is applied to the exterior of the cylinder. With thin metal, the application of the finger to the metal is sufficient to impart motion.

These motions are probably due to the same cause as that of the unscreened fan (fig. 6). The screen radiates the heat it receives from the impinging ray; the air next the screen is warmed and made to ascend, and is replaced by colder air advancing on all horizontal planes. The course of the currents is determined by the form of the recess enclosed by the screen; when the form is circular or snail-like, a well-defined whirl or eddy is established, and so continuous rotation is imparted to the vane or cap. The movements caused by a screen heated before being placed round a vane, or subsequently heated at one or more points by the application of a poker to its exterior, probably have a similar origin. That the currents causing motion are horizontal seems proved by the fact that the fans of the vanes used were strictly vertical, and therefore not adapted for indicating ascending currents; and the light tissue caps supported on fine needle points would be apt to be lifted off their supports and overturned by ascending currents, whereas they rotate horizontally for hours together. Yet that ascending air plays an essential part in the phenomenon is proved by the fact that covering the top of a screen stops the motion.

A hot vane placed within a cold screen will rotate until it cools; so the condition necessary to secure rotation appears to be a difference of temperature between the air and the screen or vane.

Screens of various kinds were tried, of high absorptive power, like white paper and paper faced with lampblack, and of high reflective power, like bright tinned iron. All answer well, but the tinned iron best. With a bright snail-like screen the difficulty is not to get the vane to rotate but to stand still. Notwithstanding the vigorous motion of the vanes, exploration of the interior of the screens by suspended silk fibres does not reveal the existence of such powerful currents as might be expected.

A vane at rest will be disturbed by a new object, such as a book being placed near it, however gently the act may be performed in order to avoid creation of an actual draught. It will, after some seconds of oscillation, and perhaps a few complete turns, adjust matters with its new neighbour, and again become quiet. The placing of a similar book on the other side will renew the motion, which always follows the withdrawal or addition of an object. With a sensitive vane, alternate deflections to the right and left may be brought about by the shifting of books.

A comparison between these results and those obtained with the radiometer is inevitable. With modifications consequent on the attenuation of the air in the latter instrument, the action in both tending to the establishment of currents of defined direction, is probably identical.

The discharge from an influence machine, directed across the openings in the screens, will cause rotation of vanes, or caps within them, as will the establishment of draught, however created.

For the instrument consisting of a vane, cap, or sphere, within a screen, the author proposes the name of radioscope.

After experimenting with vanes and caps, it was determined to try spheres.

Some India-rubber balloons were distended and hung by fine silk threads, such as are used for suspending the needles of astatic galvanometers.

All the effects produced by the vanes and caps were observed, modified by the winding up of the thread consequent on rotation, and some curious ones in addition.

A balloon was found to invariably turn one particular face to the observer on being approached, and this face it would keep toward him wherever he moved, so that he could cause it to rotate by walking slowly round it. A lamp, kettle, or other source of heat, carried round, had the same effect. Observation showed that India-rubber balloons are never truly spherical when distended, and that one side is always a little lighter than the other, and that it was the light side that always turned to the heat. The effect may be accentuated by gumming a piece of paper or foil on one side, so making it heavier. No effort on the part of the observer can induce the paper or foil to face him. Wherever he goes it immediately retreats as far from him as it can.

If a fairly spherical balloon is surrounded by a zone of paper, hung on a fine fibre, and allowed to attain a state of rest, it will,

when subjected to heat, begin to swing to and fro, towards and from the heat, and then to rotate slowly. (Fig. 13).

This effect is increased if the zone of paper is wetted, or one of wet linen used.

Generally, a few seconds after turning on the heat rotation begins, continues for a few seconds only, ceases, and then reverses. The rotation in the second direction is much better sustained, and will continue until the force acting is counter-balanced by the winding up of the fibre.

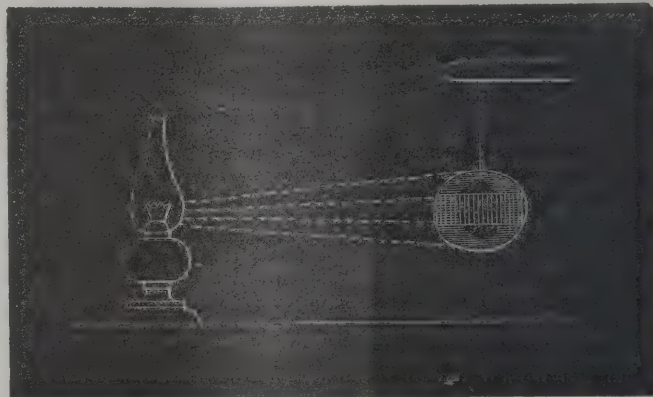

FIG. 13.

It being evident that evaporation exercised a powerful influence on the action, and the manipulation of wet paper belts being inconvenient, about half an ounce of water was put into a balloon before it was blown out, and this yielded a very convenient, and, at the same time, fairly sensitive instrument.

After shaking the water about so as to well wet the interior of the balloon, it was hung on a single silk fibre and left in the dark to come to rest, which having done, a lamp was caused to shine on it from a distance of 3 feet. After swinging a bit it turned some half a revolution to the left, stopped, and then began to rotate to the right, that is to say, in the reverse direction to the hands of a watch. After a few complete turns it paused, then continued for several turns more, sometimes pausing and going on without a reversal; sometimes reversing a little, and then continuing. When it finally stopped, the lamp was withdrawn a couple of feet, and renewed rotation was the result. Another stoppage soon occurred. The lamp was then withdrawn altogether, and rotation recommenced and continued for several more turns. The experiment was repeated many times with slightly varying, but substantially the same results. The best results were, however, attained with balloons belted with foil, and by keeping the lamp 3 feet off. When closer, rotation was not so long continued.

Suspending the balloon in a packing case, so that it is surrounded on three sides by wood, increases the uniformity of the results, although they occur markedly when suspended unscreened in a room.

The rotation produced appears to the author to be identical with that of the vanes and caps. Although the particles of bodies and gases, air included, expand when heated, indicating repulsion, yet heated bodies have a tendency to motion towards each other through the rarefaction of the air between them and the presence of the heavier air behind, and motion will occur if the friction or other restraining forces are not too great. A heated body has similarly a tendency to move towards any other between which and itself its radiation rarefies the air. In the case under consideration a cone of heat from the lamp falls on the balloon, and is radiated, rarefying the air between them, and causing the balloon to slightly approach the lamp. The perpetual endeavour which follows to adjust between this horizontal force and the vertical one due to gravity may cause the balloon to rotate, although air currents due to heat radiated from the balloon probably help. A difference of temperature between the different parts of the balloon is obviously necessary. All the results point to this stoppage and reversal after the lamp has been shining some time, and subsequent continuance. The stops and reversals give the balloon time to cool by radiating to the walls of the packing case and other surrounding objects. When equally heated all round there is no tendency to deflection and no rotation.

The resumption of motion after the withdrawal of the lamp may perhaps be explained in the same way, the heated balloon now replacing the lamp as the source of heat, and acting with the walls of the room or of the packing case. When cooled by radiation to the same temperature as surrounding objects it comes to rest.

The correspondence between the effects produced by the charging up of the vane of the radiometer and its subsequent discharge, and the heating up and subsequent cooling of the balloon is noteworthy. In each case motion is produced by the charging process, until the limit of capacity is reached, and after a dead period, corresponding to the full condition, is resumed during the discharge or cooling.

This class of experiment, to ensure success, requires the observance of stringent conditions. The room should be dark, its fireplace closed, and every other precaution taken to exclude draught. At most, two observers should be present, and they should keep as far from the balloon as possible and remain still.

The suspending fibre should be single, as deceptive rotation may be got by the untwisting of a double thread; and the balloon must be hung up and left in the dark to come to rest before having the heat turned upon it. The lamp used should be the sole illuminant in the room. For these reasons I have not attempted to reproduce the experiments in a hall like this. A balloon as truly round as possible should be used—a flat side will not pass the lamp, but oscillates alternately to the left and right before it.

The direction of rotation appears capricious, although extremely well marked and persistent when once started. Possibly it is determined by the suspending fibre retaining some directive force, but the matter has yet to be properly investigated.

By far the greater number of experiments gave rotation in the reverse direction to the motion of the hands of a watch. Sunlight suffered to fall on the balloon through an opening may be substituted for the lamp. A kettle of hot water, or even the close approach of the hand or the body to a balloon suspended by a single cocoon fibre will start rotation. Between each experiment the balloon should be lifted off and the fibre allowed to untwist. The violence with which it does this after prolonged rotation shows that the work done by the force, whatever it may be, is by no means inconsiderable.

The resemblance of the rotation of a balloon under the influence of heat applied to part of its circumference to that of the earth is certainly striking, although it may seem far-fetched to compare the world with an inflated windbag. Like the balloon, the earth receives heat on one side, and radiates it on the other, and evaporation (when the wet zone is used), combined with expansion of air, occurs in both cases. It is true the balloon has its atmosphere inside its shell, but the shell is elastic and capable of distortion in the direction of the heat, a distortion which may possibly have something to do with the motion.

The author regrets that, owing to the putting forward of the date of the meeting of the Institution in Edinburgh by a couple of months, the experiments are not so complete, nor the explanations so exhaustive and satisfactory as he should have liked them to have been.

## APPENDIX.

*Notes on Rotation of Spheres.*

India-rubber balloon	simply distended	Will deflect and oscillate but not rotate.
Do.	covered with film of water	Will rotate until film has evaporated
Do.	with zone of dry paper	Will rotate slowly and intermittently.
Do.	with zone of lamp-black paper	Will rotate slowly and intermittently; motion excessively slow.
Do.	with zone of wet paper or wet linen	Rotation much quicker, freer, and longer sustained. Many trials gave average speed as one turn in 1.25 minutes. Between the two stages of heating and cooling, motion in the same direction will continue for an hour.
Do.	with $\frac{1}{4}$ oz. of water inside	Rotation not so free as foregoing, but arrangement more convenient.
Do.	with zone of tin-foil	This gave the best results. In some cases rotation in the same direction continued between heating and cooling for over three hours, the number of turns being from 150 to 160.

With some of the arrangements, notably, the wet paper zone, a lamp is unnecessary. If the balloon is suspended breast high, the careful approach of the body so as not quite to touch will induce rotation. Balloons of French make, which may be purchased at most India-rubber shops, are best, as they are lighter and far more symmetrical than English or American.

## ABSTRACTS

## OF PUBLISHED SPECIFICATIONS, 1889.

6544. "Improvements relating to electric incandescence lamps." A. A. GOLDSTON. Dated April 16. 8d. Each of the leading in wires has a contact piece attached to it, and between the two contact pieces is arranged a cone or wedge of insulating material. To the large end of the cone or wedge is attached a metal piece which is adapted to complete the electric circuit through the contact pieces, and to the small end of the latter is attached one end of a spring, the other end of which is connected to the head of the lamp. This spring normally tends to draw the metal-piece on the cone or wedge into contact with the contact pieces, but is prevented from doing so while the carbon or light-giving conductor is intact, owing to the fact that the said carbon or conductor is sufficiently strong to prevent the leading-in wires from expanding to allow the cone or wedge to be drawn towards the contacts. Should, however, the carbon or light-giving conductor be destroyed, the cone or wedge and metal piece are moved under the action of the spring, and so make the desired contact. 5 claims.

6572. "Improvements in dynamo-electric generators and motors." G. E. DORMAN. Dated April 17. 8d. A dynamo-electric generator or motor constructed according to the invention consists of two castings of iron bolted together and forming a rectangular or box-like structure, each casting being one-half of said structure and being of trough section, and interiorly and against and integral with the bottom of each casting, and centrally located, is situated a pole piece, and on the ends of each casting and integral therewith are formed ends or brackets which contain a half boss, such ends or brackets when the castings are bolted together partially or entirely enclosing the ends of said rectangular structure aforesaid, when the castings are thus bolted together the pole pieces and bosses are bored out at the same time, or at the same sitting, so as to support centrally between the pole pieces an armature. 4 claims.

6675. "Improvements in electrically-driven fans." H. G. WATEL. Dated April 18. 6d. The inventor converts the rim of the fan into the armature of an electro-dynamic machine, or applies the ring armature of such a machine to the periphery of the fan, and he converts the fixed framing within or against which the fan works into field electro-magnets, or he applies such field magnets to the framing. The coils of the armature, or those of the field magnets, are connected to a suitable commutator on the axis of the fan, and thus when the machine is put in circuit with a suitable source of electricity, the fan is caused to revolve by the magnetic action applied at its periphery. 2 claims.

7856. "Improvements in electrical transformers." W. C. JOHNSON and S. E. PHILLIPS. Dated May 10. 8d. The inventors construct the core of thin soft iron plates or laminae separated from each other either by being coated with a varnish containing French chalk, or by the interposition of paper, such plates being so formed as to afford angular or chamfered faces at the ends of the core. After winding upon the core so formed the primary and secondary coils, they surround them with bars similarly built up of thin plates, having a curved or angular or U-shape at the ends formed either by bending or stamping, and which have angular or chamfered faces so formed as to fit accurately against the chamfered faces of the core, the whole being thus made to present the shape of a closed loop or chain link, with a bar, constituting the core with its coils, passing across its middle, the separate plates forming the loop and core lying either parallel to the plane of the loop or at right angles thereto. 5 claims.

9166. "An improved electrical repeater and commutator, to indicate the normal position and the movements of railway or other signals, slots, and the like." D. WELLS. Dated June 3. 8d. Claim:—1. The obtaining of indications on the electrical repeater of three or more distinct and different movements of the signal arms, rods, slots, and the like; using a single-line wire, and with the battery placed in the signalman's box; by bringing a resistance coil or coils into circuit between the commutator and the "earth" connection, and providing an adjustable supplementary backweight or check in the electrical repeater to ensure accurate indications.

9241. "Improvements in electric meters." A. A. CAMPBELL SWINTON. Dated June 4. 11d. The inventor causes a suitable body to vibrate reciprocally in unison with the alternations or periods of the current, the amplitude of such vibrations being proportional to the strength of the said current, and he causes the vibrations of the body to actuate a suitable recording or counting apparatus in such a manner that the said counting apparatus is moved forward at each vibration through a space proportional to the amplitude of the vibration, and consequently to the strength of the current, so that, the periodicity being constant, the counting apparatus in a given time is moved through a space proportional to the total current that has passed during that time. 5 claims.

9571. "Arrangement of circuits and apparatus to be used in connection with telephonic communication." J. E. KINGSBURY. (A communication from abroad by F. E. Welles, of Antwerp.) Dated June 8. 8d. Consists in the arrangement of the circuits and apparatus, so that the annunciator drop of one subscriber is cut out of the line, and only one spring jack is used for each subscriber. 8 claims.

9917. "Improvements in switches used for electrical purposes." F. B. NICHOLSON. Dated June 17. 6d. The inventor uses a centre contact piece, turned taper, and working in suitably constructed contact pieces after the manner of a gas or water tap, and so arranged that when the centre contact piece or bar is in one position that the metallic or electric circuit is complete or in another position it is broken. 2 claims.

## CHOOSING A RUBBER BELT.

By ROBERT GRIMSHAW.

THERE having been expressed a desire for a table which would show about how much rubber belt cross section there was needed to carry various horse-powers at various speeds, the following table (*India-Rubber World*) is offered as being convenient and practical for horse-powers from 10 to 100 inclusive, and for belt speeds from 2,000 to 2,750 inclusive. The belt is supposed to be fastened with single leather lacing. Doubling the lacing adds about one-eighth to the driving power, other things being equal, and of course calls for only about eight-ninths as much cross section for a given horse-power. If the joints were riveted there would be required only five-ninths as much belt for a given power.

BELT CROSS SECTIONS.

Horse-power.	Belt speeds.		Feet per minute.	
	2000	2250	2500	2750
10	·7	·62	·56	·51
15	1·0	·7	·8	·8
20	1·4	1·2	1·1	1·
25	1·7	1·6	1·4	1·3
30	2·1	1·9	1·7	1·5
35	2·4	2·2	2·	1·8
40	2·8	2·5	2·2	2·
45	3·1	2·8	2·5	2·3
50	3·5	3·1	2·8	2·5
55	3·8	3·4	3·1	2·8
60	4·2	3·7	3·4	3·1
65	4·5	4·	3·6	3·3
70	4·9	4·4	3·9	3·6
75	5·2	4·7	4·2	3·8
80	5·6	5·	4·5	4·1
85	6·	5·3	4·8	4·3
90	6·3	5·6	5·	4·6
95	6·6	5·9	5·3	4·8
100	7·	6·2	5·6	5·1

Thus, if we have to carry 50 horse-power and know that we are going to have belts running 2,250 feet per

minute, we can see at once that it will take 3·1 square inches of cross-section rubber belt laced with single leather lacing, and having 180 arc of contact upon a cast iron pulley in good condition. We can make about this by having 12 inches of belt one-quarter inch thick or 15 inches of belt one-fifth inch thick; or if we know how wide we shall have to have our belt we can figure up very readily what thickness to get. Thus, if we cannot have more than a 10-inch belt we shall know very quickly that it will require 3·1 divided by 10, equal to 0·31 inch of belt thickness.

For other belt speeds than those given it will take in inverse proportion; thus, for 1,125 feet of belt speed per minute it will require double the quantity; that is, 30 inches of one-fifth inch belt, or 24 inches of one-quarter inch, and so on.

## CORRESPONDENCE.

### Accurate Measurement of Low Resistance.

Referring to Mr. A. Eden's article in the REVIEW of the 4th inst, we may mention in proof of the correctness and advantages of the methods described by Mr. Eden of "obtaining accurate measurements of low resistance by means of higher resistances in shunt" that for a number of years Messrs. Hartmann & Braun's rheostats and resistance bridges have been adjusted in this manner and thereby gained their high reputation for great accuracy. Their resistance sets of small resistance are all adjusted to their full value by a shunt of higher resistance inside the instrument, the main resistance being left a trifle too great and being silver soldered direct to the thick copper feeding wires. These instruments will therefore require no further shunts for the most accurate measurements.

O. Berend & Co.,

Representatives of Hartmann and Braun.

### Secondary Battery Manipulation.

In your issue of August 1st, Mr. Shippey points out that packing the plates with a mixture of plaster of Paris and sawdust does not prevent evaporation of the liquid. I never supposed that it did, but I pointed out in a former letter, that evaporation is greatly retarded if a little carbonate of soda be added to the electrolyte. On my own authority I should hardly have ventured to make this assertion, but my attention was first called to the fact by Mr. Probert who, at the time was carrying out a series of very careful experiments at the General Post Office on the use of sulphate of soda in accumulators, and I believe it was found that where two identical cells were standing side by side in a room during six warm months, one containing ordinary dilute sulphuric acid and the other sulphate of soda, that it was necessary twice to fill up the cell containing the ordinary dilute acid, whereas the cell containing sulphate of soda, never required replenishing.

W. J. S. Barber-Starkey.

August 2nd, 1890.

### Prof. Lodge on Alternative Path Experiments.

A passage in my communication which appeared in your last issue, owing to the accidental omission of a comma, might possibly, I think, convey the impression that Prof. Lodge was one of the scientific experts who gave evidence in the late case of King, Brown & Co. v. Anglo-American Brush Corporation. Perhaps you would kindly allow this letter to appear in your columns to correct any misapprehension to which the omission of the comma might give rise.

S. Alfred Varley.

## THE DEBATE ON THE TELEGRAPH ESTIMATES.

THE recent passing of the telegraph estimates was characterised by an important and interesting debate. Important—because of the magnitude of the sum involved, and the extent of the service it promotes, and interesting on account of the absence, for once in a way, of those dry details and monotonous columns of figures common to the passing of estimates generally.

There were a few complaints at the outset as to the slow development of telegraphic communication in the more remote parts of the Highlands ; a difficult matter in which to suggest any specific course ; some general remarks at the conclusion from several hon. members as to the Carté system of telegrams as observed in Paris and elsewhere on the Continent ; a system said to be cheaper than our own, but less expeditious, and therefore of doubtful value to the commercial world ; comments on the non-purchase of the telephone interest, and the question of overhead and underground lines ; but these points cannot be said to have affected the general character of the vote.

The more prominent features of the debate were those raised by Earl Compton and Sir E. Reed. Indeed, Earl Compton and Sir Edward had openly expressed their intention of bringing matters affecting the telegraph service before the House on the discussion of this vote.

Whatever the Postmaster-General thinks of what he sarcastically terms the "endeavours of philanthropic politicians" in encouraging remedial agitation, he has but little reason to complain of the splendid and effective opportunity with which they provided him for the display of his own ideas of philanthropy and justice on the occasion under notice.

Earl Compton considered the answers given in the House of Commons from time to time, with reference to the Telegraph Department, very unsatisfactory. He disclaimed party motives, and had not taken any active part amongst telegraph clerks, whose movement had

been conducted legitimately and constitutionally. What they had done had been effected without the aid of paid or political agitators.

The Postmaster-General deprecated the interference of third persons between the Department and its servants.

The noble lord, on broader than departmental grounds held that departmental servants were, after all, the servants of the public, and not of the Postmaster-General ; on that ground hon. members had a right to interfere, if the exercise of constitutional and legitimate methods had failed to remove complaints of improper treatment.

Earl Compton evidently feels that the responsibility of the member to his constituency is of as much importance as is the responsibility of a minister of State to the House. Few will deny the soundness of this principle.

Proceeding into details of work, pay, and promotion in the Telegraph Service throughout the country, the noble lord displayed a surprising mastery of his subject, his knowledge of details being extensive and accurate. He complained of evasive replies ; of a difference between "Hansard" and *Times* reports, and preferred the latter. With reference to public meetings, he strongly advised the Government to allow civil servants to meet without interference, and took up much of the ground held by us in our leader of the 1st inst. He acknowledged that the Postmaster-General's scheme was infinitely better than he expected ; but was the Fawcett £190 class to be replaced by a new £160 class ?

This is the point on which the whole success of the new scheme turns. It is the point, too, which is still in abeyance.

Lord Compton dealt at some length on these and a number of other points, and, in moving the reduction of the vote by £150, said though the Postmaster-General had had a great deal of trouble, he thought much of it was due to his want of sympathy with those under him, but he still had a great opportunity of

reinstating himself in the affections of those over whom he was placed.

The noble lord's remarks were characterised by the temperate and yet candid manner in which they were presented, and he had a sympathetic following throughout.

Sir E. Reed, true to his promise, dealt forcibly yet fairly with what is known as the "Cardiff exiles" incident. Our readers will probably remember the circumstances of the case, and we need not reproduce them here. Sir Edward took up a very strong public position at the time, and from that position he has not swerved. He, too, disclaimed party aims, and said he was not anxious to make himself a medium for ventilating grievances in that House; and here he gave one of his cutlass-like slashes, just by way of a change, adding, particularly during the *régime* of the present Government. While he declined to unduly harass the Government, yet he thought there had been a desire to exercise arbitrary authority; but in this age discipline was not to be maintained by such measures. The House cheered this sentiment. He dealt trenchantly with the "exile" question. He had gone into the charge brought against the men; that charge was entirely without foundation. He strongly disapproved of the restriction of public meeting; any Post Office official inviting half a dozen of his colleagues to dinner, at which matters of interest to themselves were discussed, would be liable to dismissal.

The Postmaster-General had seen the gross absurdity of any such regulation.

By responding to the appeal to remove the grievances which Post Office *employés* were suffering under the Postmaster-General would probably save them the trouble of dividing on the vote. Another hon. member pointed out, as we have already done, that the order of 1866 was a dead letter.

The Postmaster-General rose, primed and loaded, apparently, with philanthropic anxiety and goodwill. In no other way can we record the spirit of his reply to his Parliamentary assailants.

We have already said that the Postmaster-General has but little reason to complain of the splendid opportunity held out to him by "philanthropic politicians," amongst whom he includes, presumably, Lord Compton and Sir Edward Reed.

Whether he does, or whether he does not, he nevertheless owes these hon. members a debt of gratitude. He had such an opportunity of vindicating his anxious zeal in the interests of telegraph clerks, that the absence of Lord Compton and Sir Edward Reed from the debate would have been little short of a catastrophe for him.

He hoped to maintain the temperate tone displayed by the noble lord. In sorrow, with just the necessary dash of anger, he rebuked the noble lord for disparaging "Hansard." Notwithstanding "the cannonade by insolent vituperation hurled at the head of the Department," complaints would receive the favourable consideration of the Government.

He hoped he had abstained from the use of irritating language. He thought it strange that he, who had been

the only Postmaster-General since Mr. Fawcett had been able to secure for the telegraphists permanent benefits, should be attacked as one guilty of unsympathetic and arbitrary dealing. He was happy to think, however, that he had been able to give to the telegraphists substantial proof of his consideration. On the subject of the prepared evidence for the Royal Commission, and which was at first sent through the "higher officials," the Postmaster-General was hazy and uncertain. He did not know much about that case. He admits, doubtless, that it was urgent. On several other points a want of knowledge also provided a ready escape.

The Postmaster-General then graciously took the House into his confidence, gloriously detailed the reforms and concessions in his scheme, and pathetically remarked that he had done all he could to show his regard for those under him.

The House heard these concessions in an appreciative spirit, as also the statement that with reference to the vexed question of maximum pay in the Central Department, telegraph clerks would find that their position would not be damnified, but improved. The Postmaster-General, notwithstanding all these advantages, is glad that he has not got to do the work of a telegraph clerk. Telegraph clerks ought not to lose sight of these statements.

Continuing to display a broad and almost amazing philanthropy, on the subject of public meetings, the Postmaster-General said the new regulations were intended to express to the servants of the department the "benevolent disposition" of their superior officers. This "benevolence" does not seem to extend to reporters who are not "official," as the Postmaster-General doubts the accuracy of their reports, and in this matter it will be seen that he, like Lord Compton, finds considerable variance amongst reporters.

In fact the Postmaster-General appeared to be running over with amiability, and the last good natured volley, in what many will call a remarkable speech, was made up of expressions of justice, kindness, benevolence and goodwill to everyone in his great department, and which department he ventured to hope he had not unworthily administered. It is not surprising that this speech disarmed further opposition, and that the vote was agreed to without a division.

From rebuking the "philanthropic politician" it will be seen that the Postmaster-General has arrayed himself from head to foot in a gorgeous and resplendent mantle of philanthropy. We trust the texture of this garment is not too transparent.

It remains for him now to see that his scheme is not tampered with by those who come between him and those to whom he has expressed such unbounded goodwill.

It will be worth his while to prevent delay in the general application of his reforms to the telegraph service, and to be careful that officialism does not underrate those points which have enabled him to pose, in what it is to be hoped is something more than a well simulated philanthropy before the House of Commons and the country. Already we hear of men being

punished for what they have said, and also of one man's dismissal on this score.

Many will ask if this is a specimen of the exercise of that "benevolent disposition" referred to in the Postmaster-General's speech.

If the whole thing is not an absurd and ill-timed parody, the Postmaster-General will see that his deeds outside the House are equal to his promises in; it will then be fully admitted that a little practice has lent additional value to much precept.

## ELIHU THOMSON'S NEW ALTERNATOR.

IN designing the machine, which figures on another page, the main object seems to have been to avoid the use of moving coils in an alternator having iron in its armature. The only machine made in this country and designed with the same object is, we believe, the alternator of Mr. Kingdon, about which, however, there has been up to the present a remarkable scarcity of data. But the idea is by no means new. In 1883 the late Mr. Charles Lever designed a machine in many respects similar to that of Professor Thomson, which was made for him by Messrs. Paterson and Cooper, and when finished, tested at their works.

The magnetic wheel or rotating pole-piece consisted of a star-shaped piece of wrought iron, like Professor Thomson's, but with eight spokes, while the fixed coils, 32 in number, arranged 16 on each side of the wheel, were wound on cores formed of split tube filled up with iron wire and attached to cast iron ring cheeks. The star wheel was carried by two upright magnets, and had all its spokes of the same magnetic polarity, while the lines of force completed their circuits in the machine by passing from the spokes through the cores of the fixed coils, then from the ring cheeks to the sole plate supporting the two magnets.

The points in which that machine resembled this of Prof. Elihu Thomson will be at once observable. It remains but to add that, when it was tried, Mr. Esson proposed a modification which would have made them almost identical, consisting in substituting for the two circles of coils on the sides of the spokes, one circle only to be wound on cores projecting inwards from a ring outside the spokes. But after experimenting for some time, Mr. Lever gave the machine up; for what reason we do not know. That he had a fairly clear notion of what he wanted to do is certain, though consequent on the state of knowledge at the time, his ideas were but imperfectly carried out. The magnetising coils induce in these machines a field having several separate paths, each of which is intercepted by a fixed armature coil. There is in each path a considerable air gap, and it is the function of the magnetic wheel to close and open in succession these gaps, so determining the successive magnetic paths the lines shall take, and inducing an E.M.F. in the fixed coils. Though there is no actual reversal of magnetism in the coil cores, there is a considerable surging of the field, and to avoid the heating which would otherwise result,

both the magnet wheel and the coil cores require to be laminated. This is done in both the Zipernowski and Kingdon machines, which Thomson's, to some extent, resembles.

*Invention made Easy.*

SEVERAL American exchanges just to hand give descriptions of converters and dynamos, devised by a Mr. De Castro, of New York, having their cores made up of iron filings. It is evident from the drawings which accompany the descriptive matter that the information given has been culled from a patent specification, and not derived from the results of practice. Respecting the construction of dynamo armatures we read that "experiments which the inventor has made lead him to believe that by the employment of cores of subdivided iron or iron filings in lieu of solid cores, he can secure inductive effects of much greater intensity than heretofore and effect a considerable economy of electric energy and insure the conversion of a greater number of lines of force or energy than has heretofore been possible." Mr. De Castro must be sadly behind the time, both with regard to subdivided iron and also filings. Of the former it is unnecessary to speak, and of the latter we need only remark that cores so made are absolutely useless. In 1879, Profs. Ayrton and Perry had a dynamo so constructed at the works of Messrs. Clark & Muirhead, and, perhaps, these gentlemen will be so kind as to enlighten Mr. De Castro on the results obtained by them, and so save him the expenditure of further time and money. Induction apparatus with iron filing cores had been tried, we believe, by Cromwell Varley, amongst others, previous to that date, and we cannot conceive how it is that so many of our American contemporaries continually insert descriptions of so-called new inventions without the slightest attempt to put the patentee on his guard against proceeding with old, abandoned, and useless ideas.

*Thunderstorms.*

THE article which we publish on another page will prove of interest to students of the phenomena of atmospheric electricity. There is no doubt that Prof. Oliver Lodge has recently done much to awaken an interest in the action of lightning, and it is just such papers as Mr. Hazens which are required to give one a good idea, in popular form, of the complex nature of thunderstorms.

*Electric Torpedoes.*

ALTHOUGH the Edison-Sims torpedo has been previously mentioned in our pages, it has not hitherto been noticed in such a complete manner as in this issue. It will be found interesting not only to military and naval readers, but also to the electrician.

*Open to Doubt.*

A TELEGRAM from Washington, dated August 9th, reads as follows:—"In view of the universal interest aroused by the Kemmler execution, an accident which occurred to-day to an *employé* of an electric light company at Washington has evoked great attention. By an inadvertence the man received a shock of 2,000 volts. He became

instantly insensible, but soon recovered, though the places where the current entered and left his body showed marks of burning, and were very painful." It is easy to get such a paragraph as this noised abroad with a view to show that there could have been no certainty that the electrical plant used upon Kemmler would send him into eternity swiftly and painlessly; but what is there to prove that the Washington workman received a shock from a pressure of anything like 2,000 volts? Moreover, we believe that the Westinghouse high tension system is employed in Washington, so the story of this wonderful escape from death may be open to various constructions.

Photographs of  
Water Drops.

THE demonstrations given by Mr. C. V. Boys of his photographs of falling water drops are well known, and Lord Rayleigh recently remarked that it had never occurred to him as being possible to obtain enough light from a single spark to photograph the drops as Mr. Boys has done, and he attributed this success to the fact of his using no lenses, which would absorb the ultra-violet rays. It is not, however, so generally a matter of common knowledge that Mr. P. Lenard succeeded very well some years ago in photographing water drops, falling through air, with single sparks, the light of the spark passing two glass lenses and the objective of a camera which gave magnified images. Copies of Mr. Lenard's productions appeared in the *Annalen der Physik und Chemie*, Vol. XXX., 1887, and show all the forms obtained by Mr. Boys. It may be interesting to state that Mr. Lenard has a paper in the same journal, No. 4, 1890, entitled:—"Leitungswiderstand von Wismuthdraht im Magnetfelde für Constante Ströme und Elektrische Oscillationen."

Too Modern.

*Modern Light and Heat* is too modern. In its issue of the 31st ult., we note the following:—"The electric railway accident in Boston on Saturday last by which two horses were killed was certainly an unfortunate one. It is a well-known fact that dumb animals, horses in particular, are of very sensitive nervous organizations and unusually susceptible to the electric current. That the public need have no more fear of the current since this accident than before, is substantiated by the fact that there is not a single case on record where a human being has been killed by a 500 volt current." Now we know of a death which occurred in this country some years ago from a continuous current machine which was running at one of the South Kensington Exhibitions, and when the difference of potential was measured between the places touched by the victim it was found to be 500 volts only. Again, deaths have occurred from alternating current Gramme machines supplying electrical energy to Jablochkoff candles, arranged on separate circuits of five each, the difference of potential necessary to keep the lights burning not exceeding 250 volts.

Telephonic commu-  
nication between  
London and Paris.

THE rumours which have been so long floating about in the air concerning this communication are gradually shaping themselves into something tangible. Already, we believe, considerable progress has been made on this side of the water with reference to the matter, materials having been got in hand for the purpose, and we believe that what delay is taking place is wholly due

to the authorities on the French side. The French Chamber has now, however, unanimously voted the expenditure of 400,000 francs towards the expense of establishing the telephonic line, and we may, therefore, expect rapid progress to be made. Of the possibility of working between the two capitals there can be no doubt, it is simply a matter of proportioning the dimensions of the cable cores and the aerial conductors, so as to bring the "KR" well within the value that it is known will give clear speaking, and this will be attainable without having them of very unusual size.

THERE has not been a great rush on the part of the clergy and parishioners of the various churches to have the electric light installed in these sacred precincts. Of course, many reasons could be given for this. It would seem, perhaps, inadvisable to erect special plant, but in the case of a church or place of worship being in the neighbourhood of a central station, the question is a simple one. This, no doubt, has influenced the vicar and churchwardens of St. Jude, Kensington, who have concluded arrangements with the House-to-House Company, as notified in another column.

Cable Laying made  
Easy.

THE *Bootle Times* has a remarkable contributor to its columns, and his articles on "Submarine Navigation" have been reprinted in pamphlet form. We do not think that this literary giant has even a method in his madness, as witness the following plan for utilising submarine boats in cable laying operations:—"The saving in time and cost of laying deep-sea electric cables, if these cables were guided to their resting place by a submarine vessel, would pay over and over again for the cost of the boat, and we should hear very little of disconnections and fractures in mid-ocean. The indirect gain would doubtless be much greater than even the saving in cost of surveying, laying, and subsequent repairs."

The Compound  
Winding Case.

IT is with regret that we learn of the intention of the Brush Electrical Engineering Company to appeal to the House of Lords against the judgment in the Scotch Courts. We can scarcely hope that the electrical trades will make any effort to resist the application of the company, because it is probably thought that even if the appeal is successful they have not much to lose considering that the duration of Brush's patent is nearly at an end; however, it must not be forgotten that there may be such an infliction as the payment of back royalties. We would gladly see some friendly pressure brought to bear upon the company, for after being fairly and squarely beaten on two occasions the present intimation looks too much like the last throw of the gamester, and people may be apt to think that there are other motives than the mere desire to sustain Brush's patent to account for the attitude which the company has seen fit to adopt; indeed, it seems possible that financial considerations may have had considerable weight in bringing the directors to their decision. Mr. Varley has on another page again drawn attention to this matter, but as the above remarks were penned before his copy reached us, we do not hold ourselves in the least degree responsible for his utterances, which must naturally be of a partial character.

## FIELD'S MERCURY THERMAL CUT-OUT.

THE protection of telegraph and telephone apparatus from abnormal currents, says the *Electrical Engineer*, New York, has led to the construction of a large number of cut-outs, both electro-magnet and thermal in their nature. In order to avoid the introduction of an electro-magnetic device which might introduce retardation, and, on the other hand, to overcome the objection to lack of uniformity and fragility in fine fuse wires, Mr. Stephen D. Field has recently invented an ingenious cut-out in which mercury is employed as the fusible, or rather volatile, material. Another object aimed at is to obtain such a construction that upon the cessation of the abnormal current the circuit to the instrument is automatically restored without the replacement of any material in the cut-out.

The simplest form of Mr. Field's cut-out is illustrated in the accompanying engraving, fig. 1. It consists merely of a glass tube with a fine bore, which is filled with mercury, and has two conducting wires sealed in at the ends. The passage of an abnormal current heats the mercury, vaporises it, and the pressure generated bursts the tube, thus rupturing the circuit.

In order to provide for the automatic closing of the circuit above referred to, the construction shown in fig. 2 is employed. Here a chamber is placed at one end of the tube, which is part filled with the mercury. The air, which occupies a portion of the chamber, being an elastic medium, allows the expansion due to the vaporisation of the mercury in the capillary portion to take place without rupturing the structure, as the air becomes compressed and the separation of the column of mercury in the capillary tube can take place, thus opening the circuit in a reliable manner without destroying the apparatus.

FIGS. 1, 2, 3.

Another form of cut-out, shown in fig. 3, is similar to that shown in fig. 2, except that instead of leaving an open air-space in the chamber, a rubber ball filled with air is placed in it and the chamber completely filled with mercury. This prevents the escape of the air from the chamber into the capillary tube in transporting or handling the apparatus, while affording a sufficiently elastic medium to preserve the apparatus from destruction by the vapour-pressure generated in its operation.

Among the practical advantages claimed by Mr. Field for this form of cut-out, are first, that, if using only pure distilled mercury, it is possible to have absolute uniformity in the conductivity of a given size of cut-out. Again, the construction of capillary tubes of glass has reached such a stage of perfection that it is entirely practicable to have a given diameter uniformly reproduced; and, furthermore, the diameter may be very much smaller than it is possible to draw any of the known fusible wire metals or alloys. Again, mercury has a very high coefficient of resistance. It therefore becomes possible and entirely practicable to construct thermal cut-outs of this character so as to permit an exceedingly small fraction of an ampère to volatilise the mercury at the point of least diameter, and the

action will take place invariably at the same critical temperature. We have seen the cut-out in operation, and it seems to fulfil all the claims made for it by Mr. Field.

## NEW CABLE RAILWAY.

A NEW cable railway, in which electricity takes an important part, has been opened on the Monte San Salvatore, in Switzerland. The line commences a few yards above the level of the Lake of Lugano, with a gradient of 17 per cent., crosses the cutting of the Gothard railway by means of light iron bridges, and reaches the middle station at Pazzallo, with a gradient of 38 per cent. in 540 yards. The working plant is installed at this station, from which the second stretch of single line is continued to the summit of the mountain. This portion of the line begins with curves of 325 to 433 yards radius, with a gradient of 38 per cent., and terminates 26 yards below the summit. The total length of the railway, which is of one metre gauge, is just over one mile. In the middle of the track is a double rack rail on the Abt system. Two passenger cars run on the railway in such a manner that when the one on the lower portion is ascending, the other on the upper line is descending.

The track rails are bolted to sleepers laid on a masonry foundation. The cable consists of a cast steel wire rope  $1\frac{1}{2}$ -inch diameter, running over grooved pulleys at the working middle station. Throughout the whole length of the line the cable is supported at intervals of from 13 to 16 yards by means of rollers hollowed in the middle. These rollers are 16 inches long and 8 inches in their smallest diameter. Larger rollers, made of iron and lagged with wood, are used round curves in order that the bite of the cable may be increased. Each car weighs  $4\frac{1}{2}$  tons, and contains four compartments, accommodating, in all, 32 passengers. The cable is attached to the underside of the car on one side. Each of the two axles to each car has fixed to it two rack wheels which engage with the before-mentioned rack when the car is in motion. Fixed on each axle are two brake pulleys, which are connected by means of two chains with two pairs of brake blocks. One of these brakes is connected with a crank lever on the driving platform by a shaft and suitable gearing, whilst the other three brakes are automatically applied if the cable becomes slack or breaks. The latter can also be worked by the driver pushing a lever with his foot. When either the hand or automatic brakes are used, they are applied to the axles of the car, thus preventing their revolving, whilst the rack wheels keep the car in a stationary position.

The working station at Pazzallo contains a 40 H.P. motor, series wound, running at 700 revolutions a minute. A 50 H.P. portable boiler and engine is provided as reserve, in case of repairs being made at the water-power station, or if a breakdown should take place. The motor or engine, as the case may be, drives, by means of belting, a countershaft, running at 138 revolutions. On this countershaft are fixed two bevel wheels and two friction wheels. A second countershaft, placed at right angles to the first, has arranged at one end a bevel wheel, which engages with either the one or the other of the two bevel wheels on the first shaft, and causes the second shaft to revolve in either direction as desired. There is also provided a third shaft, upon which the large driving pulleys revolve. The second shaft carries two brakes, one being for hand regulation, and the other being applied automatically when the cars are at the middle station, by the vehicles pushing over two levers. The working station is in charge of an engineer, who operates the hand brake and a regulating wire resistance, whilst an ammeter at the upper station controls the current. The two termini and the middle station are connected by telephone, and the latter is also in telephonic communication with the power station at Maroggia. Elec-

tric bells serve to announce the arrival and departure from the termini to the middle station, and *vice versa*. Throughout the whole length of the railway is arranged, almost in contact with the outside roof, an electric conductor which, on the driver moving a switch, closes a circuit. This contrivance permits of signals for backward or forward movement of the car being transmitted to the engineer at the working station.

The power for operating the railway is obtained from a fall of water, which is led down an iron tube 20 inches in diameter, and 370 yards long. The available power is estimated at 700 H.P., and the lower end of the tube terminates at the generating station, which is situated near the Maroggia station at the south end of the Lake of Lugano. At present the water-power is only used to actuate two Girard turbines having horizontal axes, and driving two Oerlikon dynamos direct. One of these dynamos is a continuous current machine, and the other an alternator having its exciter placed on the same spindle. The continuous current dynamo is used for transmitting the power, whilst the current from the alternator is, by the intermediary of transformers, used for lighting the town of Lugano and the cable railway stations. The alternator, which runs at 600 revolutions at an E.M.F. of 2,000 volts, supplies current to 1,500 16-C.P. lamps, which are installed in the local hotels, restaurants, &c. The price for light is  $\frac{1}{4}$ d. per lamp hour.

The continuous current dynamo is series wound, runs at 700 revolutions, and has an output of 22 amperes at 1,800 volts. The machine has been built for delivering 60 H.P., and is automatically prevented from being overloaded. The current from this dynamo is led to the motor at the Pazzallo station by 5 mm. copper wires arranged on the two-wire system, and carried on oil insulators placed on poles. The loss in E.M.F. at full load amounts to  $16\frac{2}{3}$  per cent. Thus the motor receives 22 amperes at 1,500 volts, this giving an output of the motor of 40 H.P. and an efficiency of 66 per cent. The distance from the generating station to the motor is about five miles. Suitable regulating apparatus is provided at the Pazzallo station. On ordinary days there are four journeys up the mountain and four downwards, but on feast days and at holiday time the cars make 24 journeys. The time occupied in transit from one terminus to the other—the speed being one metre per second—is about 30 minutes. The fare is 2s. 6d. for the up, and 1s. 3d. for the down trip, or 3s. 3d. there and back; on holidays these charges are reduced by half. The total cost of the installation, exclusive of conductors and turbines, has been £24,000. The undertaking has been carried out by Messrs. Bucher and Durrer, of Kägiswyl, and the railway was opened a few weeks ago.

#### THE NICHOLS PATENT LAMP HOLDER.

MOST of our readers must have often remarked on the clumsy appearance given to arc and other electric lamps which required to be lowered to replace the carbons, or for cleaning, by the long loose loop of cable

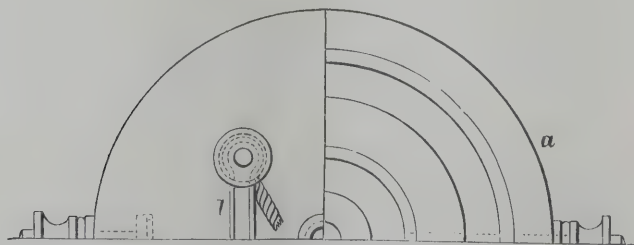

FIG. 1.

hanging at the side, as illustrated in fig. 4, the dotted position showing the lamp lowered for adjustment and the upper position showing it when working.

The necessity for this slack cable may be entirely avoided by the use of Nichols patent lamp holder, which we illustrate in figs. 1, 2, 3. Fig. 1 being a half plan, one quadrant showing the terminal and the other

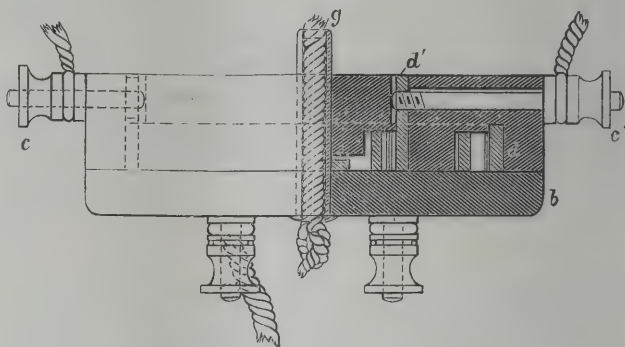

FIG. 2.

showing the inner face. Fig. 2 is an elevation half in section, and fig. 3 a plan of the inner face of the lower half. The holder consists of two parts, *a* and *b*, made of slate or other non-conducting material, the part *a* is to

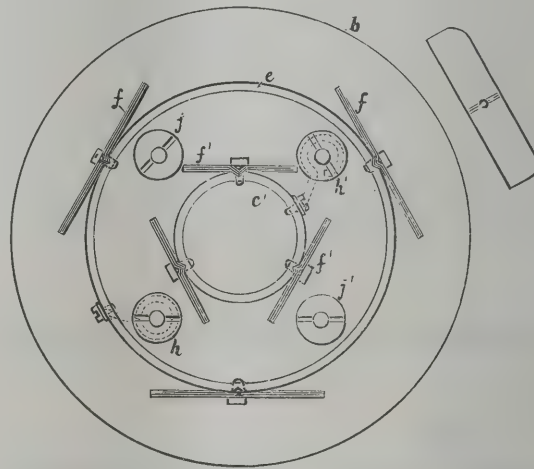

FIG. 3.

be fixed to the ceiling or roof from which the lamp hangs, and the part *b* carries the terminals to which the lamp is attached.

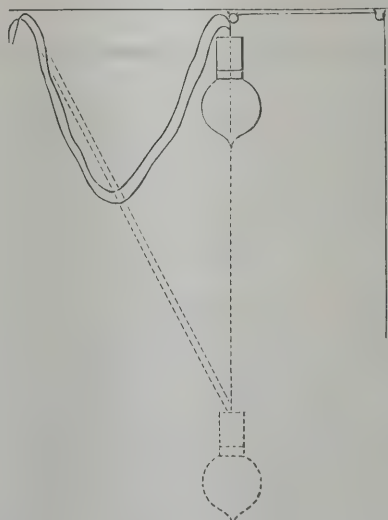

FIG. 4.

The part *a* is provided with two terminals, *c* and *c'*, to which the main leads are attached and each terminal is connected to a gun metal ring, the terminal *c* to the

outer ring  $d$ , and  $c'$  to the inner ring  $d'$ . The part  $b$  is, as will be most clearly seen in fig. 3, provided with two rings,  $e$  and  $e'$ , each fitted with contact plates,  $f$  and  $f'$ , made of thin sheet copper or gun metal which make connection with the rings,  $d$  and  $d'$ , of the part  $a$  when by means of the cord,  $g$ , the part  $b$  is drawn up. Each ring,  $e$  and  $e'$ , is in electrical connection with one of the terminals,  $h$  and  $h'$ , and between the terminal  $h$  and that marked  $j$  is fixed a fuse,  $l$ , fig. 1. The terminal  $h'$  is connected to  $j'$  by suitable wire and the lamp hung from the terminals,  $j$  and  $j'$ , three binding screws may be used instead of four, obviously, if so wished. An

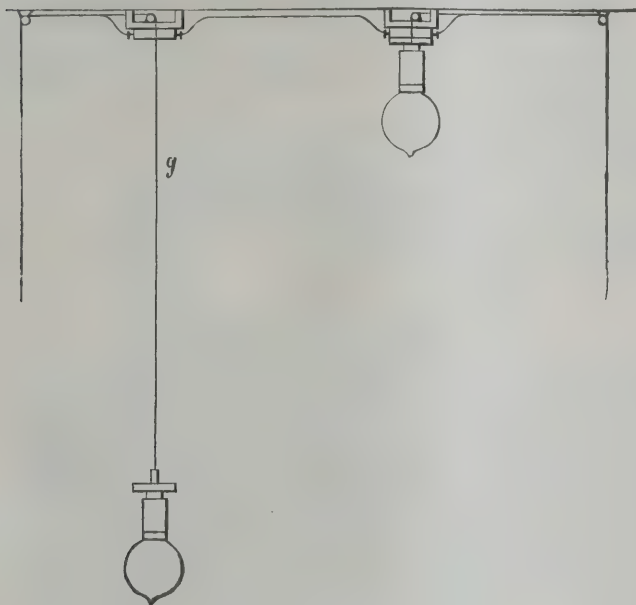

FIG. 5.

arc lamp or incandescent lamp of the Sunbeam type can be hung as illustrated in fig. 5, which shows one lamp lowered by means of the cord,  $g$ , and the other drawn up into position. The cord passes over small pulleys and can be fixed in any convenient position on the wall within reach of the hand. Where these holders are used in series a switch is provided upon the fixed part  $a$  which automatically completes the circuit when the lamp is lowered.

Several of these holders are now in use in the Leeds Town Hall and municipal offices where they have given every satisfaction. We are informed that Mr. E. R. Dolby, of 8, Princes Street, Westminster, is prepared to supply any further information.

### THE REICHENHALL CENTRAL STATION.

IN May last there was opened at Reichenhall a central station which, for town lighting by transformers, is considered by the *Elektrotechnische Zeitschrift* to be very large. The necessary power is obtained from a mill brook, which is supplied with water from a weir erected in the river Saalach. The length of the brook is about 350 yards, having a fall of nearly 9 feet, and the available water amounts to from 880 to 990 gallons per second. This water actuates a Jonval turbine, yielding, at an efficiency of 75 per cent., from 106 to 120 H.P. It runs at 34.5 revolutions a minute, and transmits power, by means of toothed wheels, to a horizontal shaft which makes 121 revolutions. This shaft carries a pulley, over which passes a belt which drives an Oerlikon alternator at 600 revolutions. The current furnished by this machine is 30 ampères, at 2,000 volts, and the exciting dynamo is mounted on the shaft of the alternator. The current is led by insulated conductors to the switchboard, and the exciting dynamo energises the lamps in the generating room, with the exception of one placed on the switchboard, and which is fed from a small transformer.

The primary current is led overhead through Reichenhall to the St. Zeno Convent, a distance of nearly two miles; and then, further away, to Kirchberg, and several other localities. The aerial conductors consist of two copper wires of 6 mm. cross section, insulated by Johnson and Phillips oil insulators, and carried on masts 49 feet high. At present there are ten transformers used, arranged in parallel. Two of these are for 10,000 watts, six for 5,000, and the remaining two for 1,500 watts. The secondary current is distributed at two distinct tensions: at 100 volts for glow lamps, of which 900 are now installed, and at 50 volts for 118 arc lights. The total loss in the primary conductors is said to be 3 per cent. The installation has been carried out by the Munich depôt of the General Electrical Company of Berlin.

### PROF. THOMSON'S LATEST DYNAMO.\*

THE accompanying cut shows the details of a dynamo-electric machine so extraordinary in its structure and electrical properties as to be fairly revolutionary; a machine quite as unique in its way as the Duncan motor, to which reference was recently made in our editorial and other columns. The new machine is the invention of Prof. Elihu Thomson, and its special marked properties are total absence of external magnetic field, and almost complete freedom from hysteresis.

Fig. 1 shows a section of the machine. The revolving portion of it consists of a shaft surrounded by a massive iron cylinder, bearing on its central portion the laminated mass of iron that forms the internal pole

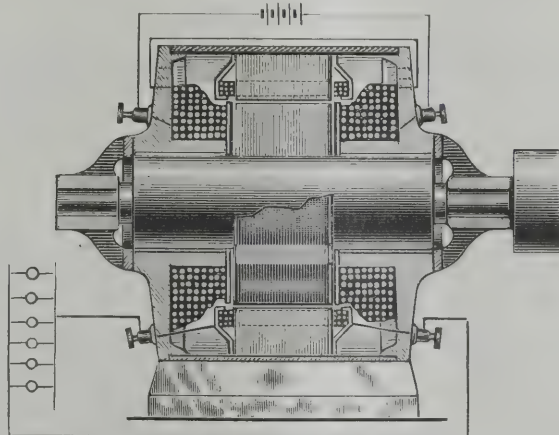

FIG. 1.

pieces. The appearance of this part of the machine is shown by fig. 3. This iron mass revolves within a pair of iron sleeves, which carry the bearings of the machine and the magnetising coils, which are thus fixed and wound on bobbins on either side of the revolving poles. The end plates of these massive sleeves are joined by a cylindrical casing of iron, completely shutting in the machine. On the interior of this casing, and immediately surrounding the revolving pole pieces, is a ring with inwardly pointing poles barely clearing the revolving ones. Looped around these poles are the armature coils. The magnetising coils of the machine are so wound as to produce, in the revolving portion, consequent poles of the same polarity in each of the polar projections. The magnetic circuit extends through the internal cylinder and its surrounding sleeves through the outer casing, and forms consequent poles of opposite polarity to the revolving ones in the polar projections that point inward. There is thus no external field whatever.

The action of the machine is as follows: The moving field poles carried around by the revolution of the core piece pass in front of the coils in which the currents

\* *Electrical World.*

are to be induced. The lines of magnetic force from these pole pieces cut transversely across the wires on the coils, since these lie in the proper direction to be so cut, or at least the sides of the coils parallel to the axis so lie, and in them are generated impulses of current. The direction of the winding and connection is such as to make the effect accumulative in the coils, so that if the polar projection passes (as in fig. 2) over the centre of one coil to that of the next, its lines of force are

FIG. 2.

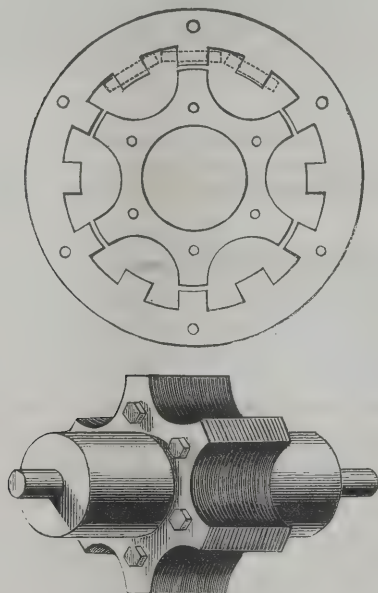

FIG. 3.

caused to cut the wire lying between these centres. Impulses of current would thus be set up in both coils, and as the coils are wound each impulse will be super-added. The number of inward pointing poles may be, as in this case, double that of the outward pointing poles; or it may be the same, when the action becomes a simple cutting in succession by the lines of force emanating from the polar projection, of one side of a coil, or of one side of all the coils taken together, and immediately afterward the other side of the same coil or set of coils.

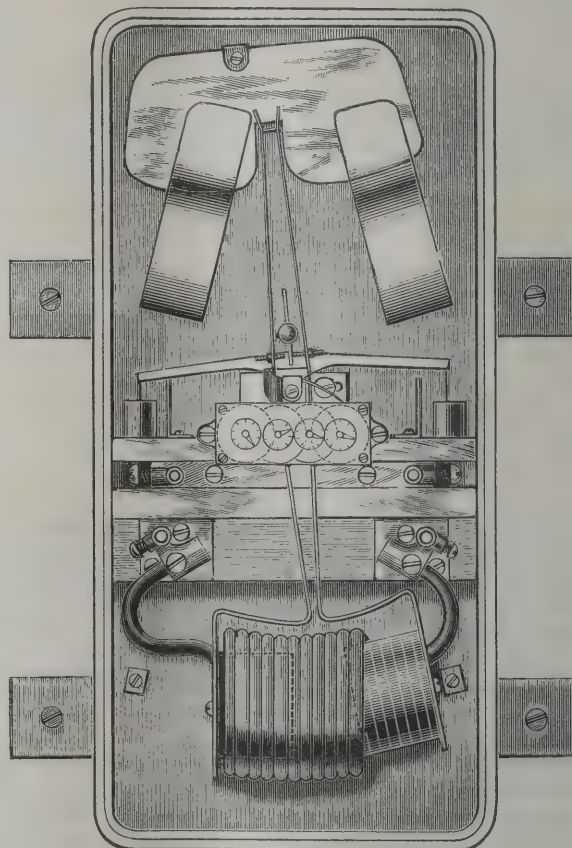

These actions will be repeated in the coils every time a polar projection passes the wire on either side of the coil, so that if there be six poles, and the revolution of the machine be at the rate of 1,000 turns per minute, there would be 6,000 complete alterations of current per minute. These actions of induction will be accomplished without reversal of magnetism in the core piece, or in the laminated ring structure supporting the coils, and hysteresis will thus be reduced to a low amount. Of course, all cannot be obviated, for the reason that there is a changing of the magnetism of the pole pieces in any case; but it will be reduced to a quantity far less than if the same mass of iron were reversed as usual. It is not necessary then to laminate either the revolving or the stationary poles, and it is obvious that the machine, although described as a dynamo, is equally applicable to the construction of an alternating motor that would possess many desirable qualities; or, by the addition of a commutator, be suited to the production of continuous currents.

We think that this description is sufficient to indicate the remarkable properties of the new machine, and although as yet no details of its efficiency are at hand, it certainly appears to be a very simple and effective form of generator or motor. The construction is especially easy and the winding admirable, since there are no moving coils, and therefore no moving contact of any sort, the wires to both field and armature being simply connected to binding posts. The machine certainly is very creditable to Prof. Thomson's inventive genius, and, unless we much mistake, will soon be heard of commercially.

### PROF. THOMSON'S ELECTRIC METER.

A VERY ingenious application of Prof. Thomson's beautiful experiments in electro-magnetic repulsion by alternating current, says the *Electrical World*, is to be found in his electric meter, of which a cut is given herewith. It is an exceedingly simple contrivance, and is as effective practically as it is neat theoretically.

This meter is a modified form of the motor type that measures the current by its direct electro-dynamic action, but, as will be seen, possesses some rather interesting peculiarities. Like most similar devices, it registers the readings directly upon dials like a gas-meter, and can consequently be read by the consumer at any time. This is no small convenience, although perhaps somewhat overestimated, for it is no guarantee of accuracy.

The arrangement consists, as shown, of a single coil of coarse wire wound along a gentle arc. This carries the main current to be measured. Immediately above it is a pendulum, mounted on knife edges, and provided at its lower edges with a pair of coils of fine wire, which are swung inside the solenoid just mentioned. The pendulum is prolonged above the knife edges, and bears at its upper extremity a light copper sheet, which swings in the magnetic field produced by the permanent magnets shown. This delicately poised pendulum is provided with the apparatus intended for registering its oscillations on the dials. The motive power is the repulsive force produced by the solenoid on the two fine coils of the pendulum. These are alternately connected as high resistance shunts across the mains of supply. The main current is thus forced through the actuating solenoid, while a derived current of small quantity energises alternately the two coils on the pendulum bob, being shifted from one to the other at the extremity of the swing by means of the commutator attached near the knife edges of the pendulum. Thus when current is turned on the meter a steady air line is set up, damped considerably by the currents induced in the copper sheet at the upper extremity of the pendulum and checked at either end of the swing by elastic stops. The possibility of using the apparatus as an energy meter is obvious, and altogether it seems

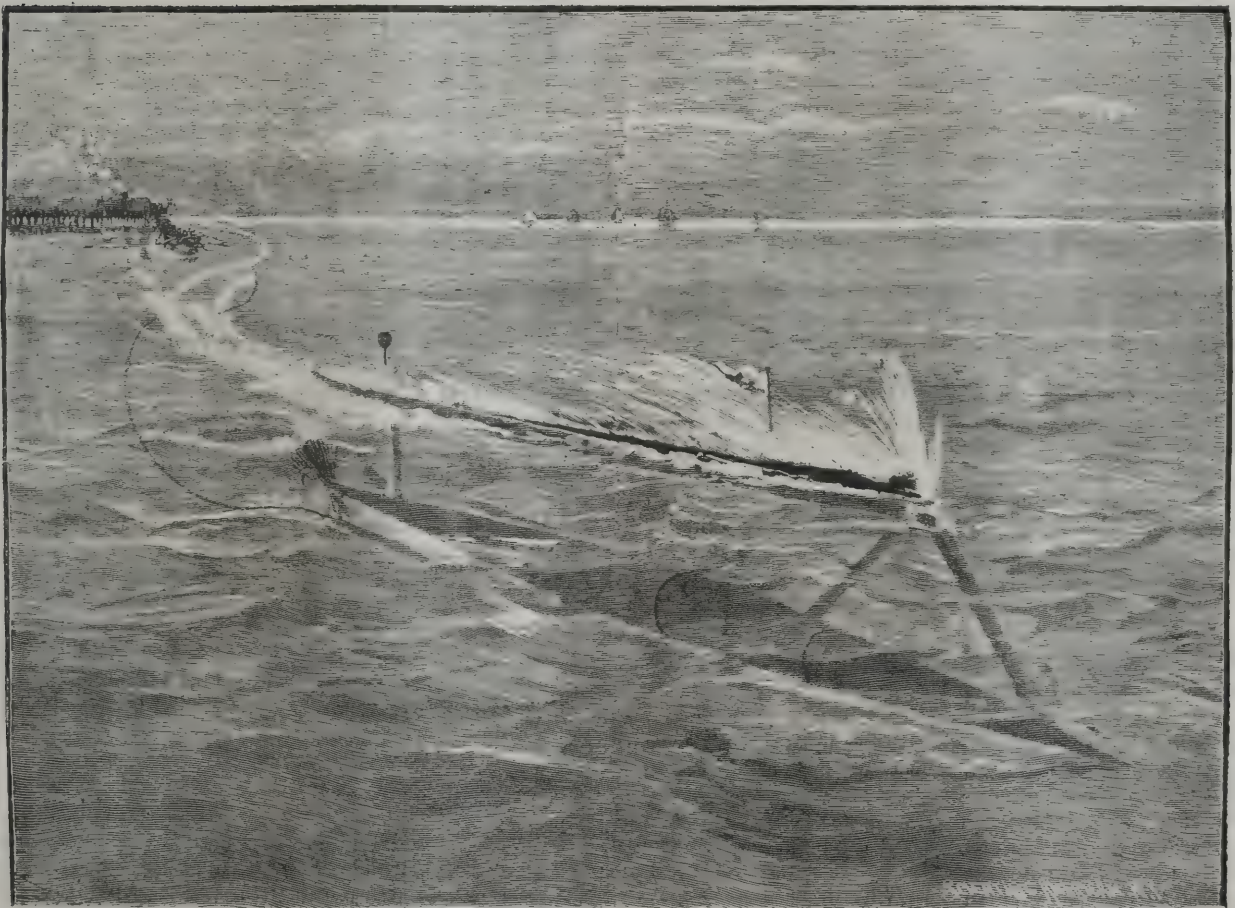

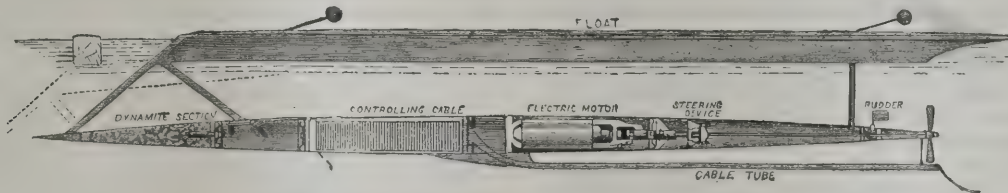

a very finished and simple apparatus for registering the amount of current passing through. It is obvious enough that slight modifications will enable it to be used for measuring continuous currents also.

### EXPERIMENTS WITH THE SIMS-EDISON TORPEDO.

ON Tuesday, July 15th, an exhibition of the Sims-Edison electric torpedo was given at Willetts Point, at the entrance of Long Island Sound, in the presence of

filled with cellulose or cork, in order to resist the effects of penetration by shot. In actual trial it has been found to be a very difficult object to hit. The cable is connected to a dynamo at the station, which may be on the shore or in a ship.

The peculiarities of its action as developed by these features may be summarised thus: As the torpedo progresses the cable is fed from out its body. The result of this is that there is no cable to be dragged through the water; the torpedo progresses, but the cable remains stationary, so as not to impede its speed. As the source of electric power is in the station, there is no limit beyond that imposed by the size of the cable and electric motor to the power which may be

a numerous gathering of representative naval and army men and other guests. We (*Scientific American*) have already described and illustrated the general features of the torpedo in this paper, and we reproduce our sectional view of the same in order to recall to our readers' mind its general construction. It consists of a cigar-shaped torpedo and motor case, within which is stowed away upon a reel from one to two miles of controlling cable. The cable is led out through a tube running parallel with the axis of the torpedo and boat to a point aft of and below the propeller wheel. Above the torpedo proper, and rigidly connected thereto, is a float possessing the general outlines of a racing shell, and provided with two sighting poles by which its course can be observed. The hull, if desired, can be

transmitted. The active explosive agent is contained in the submerged torpedo case, and in advance of the bow of the float. It, therefore, is the first portion to come in contact with the hull of a ship. The instant it touches the hull the motion of the craft will be arrested, and the electric instruments on shore will at once testify to such arrest of its course by the increased mechanical strain put upon the motor, which would at once affect the current. Finally the raking bow connection, which is seen in the illustrations, enables it to give under obstacles. This manœuvre has been subjected to a severe test, and the action of the torpedo in this way has been found to be very perfect.

As it was exhibited on Tuesday, it was worked from a shore station as shown. The torpedo was lowered

in the water and the current turned on from the switch-board. At once the craft started into action, and at a rapidly increasing rate of speed ran out into the stream. Before it stopped it had completed its course of about a mile. Under complete control of the operator on shore, it emerged from the station, and describing a long and circuitous route in the water, returned nearly to its starting point. The mile of distance was completed in about three minutes, indicating the attainment of a very high rate of speed. When in full action the hull became nearly buried, while quite a wave was thrown from the rapidly advancing bow. In some observations it has been noted that the boat went so fast as to run away from the wave it generated. All through its course triangulation observations were taken at exact intervals, in order to determine its speed. These were in charge of the corps of engineers attached to Willets Point.

The torpedo is built in four sections, which can be taken apart or assembled in 15 minutes; none of the parts weighs more than 500 pounds. The motor at full speed can absorb over 30 horse-power available for propulsion. A speed of 22 miles an hour has been obtained by it. The charge of 250 to 500 lb. of high explosive is to be exploded electrically by reversing the current. The steering is also done electrically through the agency of a polarised relay.

Its operation from a shore station is limited in extent by the length of the connecting cable. In the large torpedoes this will be two miles. In operation from a war ship, it is proposed to run two or more boats along a parallel course with the ship and close to it, receiving their motive power from the ship's electric plant. Here, as the ship and torpedoes will all progress alike, and as the electric plant on board can supply power for an indefinite period, the ship and torpedoes can keep company for almost any number of miles. When the enemy is approached the course of the ship can be arrested or its speed can be slackened, and the torpedo sent ahead or to either side at high speed, in order to destroy the enemy. For fort use a special form of casemate with conning tower and other necessary features have been planned by the company. There is little question that a number of these torpedoes could do much to defend New York harbour, at the end of the East River, between Willets Point and Fort Schuyler, and at the Narrows, from entrance by hostile vessels.

## THE ELECTRIC RESISTANCE OF GAS IN MAGNETIC FIELDS.

MY primary investigations with the action of magnetic fields upon Geissler tubes, the results of which I had the honour to place before the Academy, at the sitting of the 12th May, 1890, had yet, writes M. A. Witz (*Comptes Rendus*), to be completed; in fact, when the effects produced by varying the intensity of the field, and the position of the tube in relation to the field's lines of force had been studied, it still remained to determine the influence which a modification of the gas pressure within the tube would exercise.

My experiments were made with the aid of a glass cylinder, 2 cms. in diameter, fitted with taps, and as well adapted for compression of gas as for rarefaction; the discharge took place between two electrodes, the cones of which were aluminium. With mercury pressure, 0 cm. 6, I obtained a violet tinted discharge; at 230 cm. the result was a spark, warm, brilliant, and sustained, in the form of a flash of fire between the points; and between these two pressures the appearances were a combination of spark and discharge. Now the action of the field, as presented to the eye, varies under these different conditions; the discharge is subject to deviation in obedience to the electrodynamic laws—the spark is not; consequently, when the pressure is slight, the action should be considerable; when with a high pressure it would be *nil*.

We have now to verify the exactness of these inferences, and the following are the results obtained:—

### Outside the Field.

Pressure.	Current.	Difference of potential.
cm.	milliampères.	volts.
0.607	5.86	976
32.446	4.66	2,815
74.610	2.79	4,669
76.029	3.50	5,544
114.310	2.33	8,058
115.51	2.16	8,731
230.1	1.42	12,028

### In a Field of 7,200 Units.

Current.	Difference of potential.
milliampères.	volts.
3.91	9,787
2.75	5,857
2.04	4,719
2.05	6,919
1.44	8,097
1.27	9,487
0.74	12,539

With the slight pressure 0 cm. 6, the difference in potential was ten times greater; whereas at 3 kg. pressure the variation was, so to speak, *nil*. From this I feel justified in concluding that it is only upon the electric discharge that the fields have any influence at all.

This, which with the Geissler tube is so considerable, must then be a peculiarity of the constitution of this tube and of the rarefied condition of the gas which it encloses, since it is not to be produced with free gases unconfined.

This should result in a previous indication for the analysis of the complex phenomena observable in the Geissler tubes. The similarity between the effects produced with a magnet and by the approach of a metal conductor (nay, by approaching the finger even) leads me to a fresh explanation of these phenomena. The similarity is striking, judged by one example. Thus a tube enclosing silicic fluoride gave the following results:—

### Outside the Field.

Current.	Difference of potential.
1.50 milliampères.	2,434 volts.

### In proximity with a mass of Iron.

Current.	Difference of potential.
1.16 milliampères.	3,185 volts.

### In a field of 11,570 Units.

Current.	Difference of potential.
0.99 milliampères.	5,730 volts.

It is true the effects varied with the nature of the gas, the form of the tube, pressure, &c., but they were almost always remarked in connection with tubes of sensitive condition. The phenomenon was sufficiently general to allow of the action of the magnets being attributed to a varying in the electric capacity of the Geissler tubes. These tubes must constitute, therefore, genuine condensers, and their illumination should be the result of an oscillatory discharge of a nature similar to that of a Leyden jar, the period,  $T$ , of which is the function of the jar's capacity,  $C$ , and of the coefficient,  $L$ , of the conductor's self-induction, the resistance of which is assumed to be slight, since  $T = \pi \sqrt{LC}$ . A varying of the capacity,  $C$ , would, consequently have the effect of modifying the vibratory condition of the gas, and be the occasion of the differences observable in the luminous phenomena of intense magnetic fields.

**Lincoln and Electric Lighting.**—The Town Council has refused to grant consent to any electric company wishing to supply the light.

## ELECTROLYTIC THEORIES.\*

By Prof. G. F. FITZGERALD, F.R.S.

ELECTROLYSIS has been explained on two different theories by Grotthius and Clausius. As generally received they differ. Grotthius's theory, as generally given, assumes that the molecules in an electrolyte are both polarised and moved by the electric forces within the liquid. This seems so far untenable that it would appear that double the electric force would double both the polarisation and the motion of the molecules, and so should produce four times the electrolysis. The objection, however, assumes that we know the causes resisting the motion, and with proper, and not very improbable assumptions as to the resistance to motion depending on it and on the polarisation, a linear relation between current and electromotive force, *i.e.*, obedience to Ohm's law, seems possible. A modification of Grotthius's hypothesis in the direction of Clausius's is, however, possible. Suppose that when polarised the molecules *drew one another apart* at a rate proportional to the polarisation. This at once makes the relation between electric force and the decomposition a linear one, and so satisfies Ohm's law in the case of small currents. It also so far agrees with Clausius's hypothesis that it explains electrolysis and double decomposition as properties of the same kind. The molecules in a liquid will occasionally be arranged by accident in the proper polarised condition in a closed circuit for drawing one another apart; and if the circuit includes molecules of different kinds, there will result double decomposition. There seem to be very serious difficulties in supposing that uncombined atoms are for any finite time free in the liquid; and the supposition that it is a particular arrangement that is required before exchanges take place, and that with this arrangement exchanges take place of their own accord, seems to explain electrolysis and double decomposition without supposing free atoms to exist within the liquid. I have not assumed Prof. Armstrong's suggestion that the proper arrangement for double decomposition is a double molecule; but it seems a likely hypothesis, and one that should be investigated from the chemical rather than the physical side.

There are some other phenomena that have been explained upon the supposition that free atoms are gadding about in a liquid. Such are the lowering of the boiling and freezing points by solution of salts, and their effect on osmotic pressure. If dissociated atoms are going about in a liquid as in a gas, it seems impossible but that they must diffuse at different rates; and that this is not observed seems conclusive against the hypothesis, no matter what else the hypothesis may explain. Consider solution simply. Why does chloride of sodium dissolve in water? There must be some strong affinity between the two of a chemical or semi-chemical nature to break up the cohesion of the crystal; and it seems reasonable to assume that this same affinity keeps the molecules of NaCl moving about among the water molecules, so that they diffuse about. Now, if the forces drawing them about be independent of the nature of the molecule, most of the phenomena explained by gaseous laws are explained. Pressure of a gas depends, at any temperature, on the number of molecules, and not on their kind. This is Avogadro's law, by which molecular weights are calculated; and if the forces drawing a molecule about in a liquid are independent of the kind of molecule, the very same law of pressure would hold, the pressure forward of molecules of different kinds would depend on their number only, and in the same way as Avogadro's law would enable molecular weights to be calculated. In this connection it is well to state that some bodies may, nevertheless, be much better able to produce pressure than others, because of their being more easily polarised, *i.e.*, turned into an effective direction. A molecule

which could be easily turned into an effective direction would be about twice as effective as a molecule which went about in a higgledy-piggledy way; and one would consequently expect electrolytes to produce more, nearly double, the osmotic pressure that other bodies did. As to the changes of boiling and freezing points, they seem explicable by exactly the same hypothesis. The reduction of vapour pressure by molecular affinity of dissolved salt would depend only on the number of molecules of salt if all salts have the same molecular affinity for water; and the same would apply to the change in freezing point. Hence all these phenomena are explained without assuming free atoms and they are all explained by what can hardly avoid being a *vera causa*, namely, whatever affinities they are that cause solution, which latter is an unexplained phenomenon on the dissociation hypothesis. That it is reasonable to think that the forces keeping the molecules of salt moving about in the water are independent of the nature of the salt, appears from various considerations. In the first place, these forces are in all probability due to the residual affinities of the non-metallic elements. These same forces are probably the cause of crystallisation. These are old suggestions. That these residual affinities should be nearly the same for different combinations does not seem at all unlikely.

If a rather shaky argument in favour of its likelihood on mechanical grounds is desired, the following may deserve attention. Suppose a molecule of NaCl, for instance, at rest, or nearly so, in a crystal. Subject it to this affinity. Its velocity, after it has gone a distance,  $s$ , will be given by some such relation as  $fs = \frac{1}{2}mv^2$ . Now, for the sake of temperature equilibrium, with molecules of somewhat similar structure,  $\frac{1}{2}mv^2$  must be the same in all. It seems likely that, at least approximately, the kinetic energy of motion is proportional to the total energy, and that this is the same for each molecular group; if so, the kinetic energy must be approximately the same for different groups. Now, with very dilute solutions  $s$  must be nearly the same for different molecules, and if so we get that for temperature equilibrium  $f$  must be independent of the nature of the molecule. How this equalisation of  $f$  for different kinds of molecules comes about may be as follows. Molecules in a liquid move about among one another, but are well within the sphere of one another's attraction, as is evidenced by superficial tension and by the tension to which a liquid can be subject. A very small change in the distance apart of the molecules means, however, a very great change in the forces between them, as otherwise they would be extensible and compressible like gases. It seems likely, then, that when a salt dissolves in a liquid it requires for temperature equilibrium that the distances of the molecules should change by the very small amount required in order that  $f$  may become the same for all substances. This very minute change in distance would not sensibly affect  $s$ .

---

**Electrical Indicator of Explosive Gases.**—An apparatus which indicates with safety the accumulation of explosive gases in the atmosphere of rooms is of great importance in many trades, and especially for use in mining operations and in the transport of coal by ships. M. Eduard Stern, of Cologne, has brought out such an apparatus. It consists of an external porous clay cylinder which contains a thin metal membrane capable of upward movement. Just above the membrane is a contact screw. When explosive gases begin to accumulate, they pass through the porous cylinder and gradually raise the membrane until it comes into contact with the screw. This completes an electric circuit and sets in operation a set of electric bells. The contact screw is very sensitive and may be adjusted to any degree, according to local circumstances. The apparatus is also applicable as a fire alarm and may be fitted in any convenient spot.

\* Communicated by the Secretaries of the Electrolysis Committee of the British Association.

## THE DYNAMO AS A MOTOR.

THE easy convertibility of a generator into an efficient motor was demonstrated lately in a very satisfactory manner at the Manningham Silk Mills of Messrs. Lister & Co., Limited, Bradford. During the recent overhauling of one of the main engines, which worked the machines in the batting, shearing and finishing departments, it was found that repairs had to be made which would take up so much time that unless substituted power could be obtained these important departments would be stopped, and a number of hands would be idle. As no ordinary or ready means were available for this object it was suggested by the electrician to the firm, Mr. Edwin Preece, that the dynamo used for the lighting of this department should be tried as a motor in place of the engine under repair. Permission having been granted for this trial, the electrician, assisted by Messrs. Andrews and Preece, Limited, Borough Mills, Bradford, quickly made the necessary arrangements, and the dynamo was very shortly at work driving the shafting.

In an article which we published on June 20th, describing the installation at the Manningham Mills, it was pointed out that one portion of the mills was lighted by a "Preece" 500 ampère dynamo, driven by an independent Robey engine, whilst the other portion of the mill was lighted by a similar dynamo, driven by a clutch arrangement from the main engine of the mill (which was the one broken down). The two systems of lighting were, as explained, connected together by mains governed at each switchboard by a double plug switch, with only one pair of plugs, in order to avoid confusion; but under the altered circumstances, it was necessary to connect up the plug switch at each board, consequently a second pair of plugs had to be obtained; the arrangement was then complete, after the ropes from the flywheel had been disconnected from the main driving pulley in the shaft. The Robey engine was started, driving the dynamo attached to it and generating a current which was transmitted to the second dynamo by means of the conducting wires and the double connection of the switchboards, the second dynamo then—its brushes being reversed—became a motor, and being clutched on to the main shafting by means of its own counter-shaft, produced sufficient power to work the various machines required in the department.

The whole arrangement was completed in about an hour after the decision had been arrived at, and the machinery was started without the slightest hitch whatever. The current passing into the motor varied from 250 to 500 ampères, according to the different loads, at a potential of 115 volts; it was kept running for about 36 hours without one single stop or the slightest interruption whatever. The remarkable self-regulation and regularity of speed under different loads, was an agreeable surprise to the principals of the firm, who were so well satisfied with the new arrangements that in all probability a further development of electricity as a motor may be decided upon. This is, we believe, one of the few instances where a dynamo has been utilised to take the place of the steam motor which usually drove it, and thus enable the operations of the factory to be carried on with but the slight delay due to the necessary alterations in connection. The whole operation reflects credit on those engaged, and demonstrates the extraordinary value of the dynamo-electric machine.

## KING, BROWN AND CO. v. THE ANGLO-AMERICAN BRUSH CORPORATION.

By S. ALFRED VARLEY.

FORMAL notice of appeal to the House of Lords in the above case has, I am informed, been given. The judgment lately delivered in the Court of Appeal not only confirms and strengthens that previously given in the

Court of Sessions, but is so clear and unambiguous that I cannot think it possible that the directors of the Brush Corporation will have the support of their shareholders, generally, in spending more money over litigation.

In November, 1887, the suit of *Brush v. Crompton* was compromised, judgment in favour of the plaintiffs being agreed to, and licences accepted, and the position of the Brush Corporation in respect to compound winding was consequently very much strengthened. At this stage I intervened, and, with a view to arousing the electrical industry to resist the claims so far successfully asserted, I tried the case, journalistically, through the medium of the columns of the *ELECTRICAL REVIEW*, in four consecutive articles which appeared in December, 1887. The following passage appears in the first article:—

"In my opinion, the electric light industry has so far allowed the Anglo-American Brush Corporation to simply walk over the course, and it seems to me the industry has acted most short-sightedly in doing so. It requires no prescience to foresee, that after the trade has acknowledged the claims asserted by the Brush Corporation, by submitting to pay royalties, that the next step will be to apply for a prolongation of the patent on the ground that this *valuable* invention, due to the *genius* of Brush, has yielded no returns commensurate with the expenditure incurred in developing it. And who shall blame them for making such an application, seeing that in the circumstances I have mentioned, it would most probably be successful?"

I also analysed and called attention to the very unsatisfactory character of the scientific evidence, and the publication of my articles resulted in Messrs. King, Brown & Co. resisting the Brush Corporation, and this firm, instead of waiting the convenience of the Anglo-Brush Corporation, took the initiative by themselves, commencing proceedings in the Scotch Courts, and after being successful in the preliminary skirmishes, on the advice of the Court, they took proceedings for the reduction of the Brush patent.

The case came on for hearing in the Court of Sessions, Edinburgh, in November, 1888, the Court deciding in favour of the pursuers, with expenses, and this judgment has been sustained on appeal.

In my opinion it is simply lamentable, and indicates a sad condition on the part of scientific professors, to see a physicist so distinguished as Sir William Thomson professing to be puzzled and not able to understand a plain simple description, which the judges had no difficulty whatever in comprehending, and doing so after *practical* evidence had been given before the Court by more than one unscientific mechanic and apprentice that they had experienced no difficulty in understanding the description given in my specification. The Court declared the description of compound winding given by Brush to be the same as that given in my specification, the only difference being that I had described it more simply. Now, Sir William Thomson and his brother professors did their best to persuade the Court that the description given in Brush's specification, in which compound winding was described as a "teaser," was as plain and understandable, as they declared mine to be incomprehensible.

Now, although there is scarcely any likelihood that the judgment given in the Scotch Courts will be reversed by the House of Lords, nevertheless, until it is disposed of, it will have a baneful influence on the industry, and therefore I would suggest that the industry should unite and draw up a pamphlet, giving a plain statement of the facts; that they should issue this pamphlet in their corporate capacity to the members of the Chamber of Commerce, to the members of the engineering and scientific societies, and also request the press to notice the matter contained in the pamphlet.

In this way, at a very small pecuniary cost, moral pressure would be brought to bear on the directors of the Brush Corporation, and the shareholders would, in all probability, oppose further useless waste of money on litigation.

## REVIEWS.

*Dictionnaire d'Electricité et de Magnétisme. Premier Fascicule, A—Electrolecteur.* Avec 284 figures. Par JULIEN LEFEVRE, Professeur à l'Ecole des Sciences de Nantes; avec la Collaboration d'Ingenieurs et d'Electriciens. Paris: J. B. Bailliére et Fils, 19, Rue Hautefeuille.

It is intended that this dictionary shall appear in four parts, the last to be issued before the end of the year. The complete set will form a volume of 1,100 pages, containing about 1,000 figures. Judging from the part now before us, the whole work, when complete, will be a very valuable addition to electrical literature, and will constantly be used for reference purposes. The value of the compilation would have been considerably increased had it been made more universal; thus, for example, under the first heading, viz., "Abonnement," we have full information given with reference to the subscriptions to the telephone exchanges in France, but nothing with reference to those in other countries. Of course, to have included the latter would have increased the size of the work, and it is probably this consideration which has limited its scope. The compilers have wisely made their descriptions fairly full, *i.e.*, have not sacrificed clearness to brevity; thus we have accumulators dealt with in nine closely printed pages, with several illustrations. The information given appears generally to be fairly accurate; here and there, however, we come across somewhat strange statements, as, for instance, when we are informed that to measure the insulation resistance of a cable the latter is placed in *acidulated* water; also, that submarine cables are wound upon great *drums* on the ships. Electric lighting is dealt with in 40 pages—Messrs. Woodhouse and Rawson's work coming in for a fair share of notice; considering the almost endless sources of information there are on this subject, and the consequent extreme difficulty of condensing the available matter, the selection made is very judicious and the scope wide. Altogether, the work creates a very favourable impression, although it is distinctly written (possibly not intentionally) from a French point of view.

*Journal of the Institution of Electrical Engineers,* No. 88. London: E. & F. N. Spon, 125, Strand.

This number contains the following:—Paper on "The Treatment, Regulation, and Control of Electric Supply by the Legislature and the Board of Trade," by Major P. Cardew, with discussions on the same.—Communication from Dr. Oliver Lodge in reference to damage to cables by lightning; this latter has reference to the suggestion that condensers and cables are never damaged by lightning, and professes to be testimony from Dr. A. Muirhead and Mr. Gott to the contrary; the testimony does not appear to be very conclusive as regards cables. The usual abstracts, &c., complete the number.

**Crystal Palace Engineering School.**—On Saturday last the certificates to successful students of the Crystal Palace School of Practical Engineering were distributed by Sir James N. Douglass, F.R.S., Engineer-in-Chief to the Corporation of the Trinity House. He referred in his address to the increasing attention given of late years in this country to technical education as a means of enabling young engineers to enter on equal terms the competition with other nations. He thought the best thing a young man could learn was that competition would follow him through life. An Englishman ought never to be afraid of competition, and if he did his work faithfully was sure of success in any part of the world. The work of the students was exhibited in the shops and offices, and as usual was very creditable, including some interesting dynamo work in the electrical section.

## NOTES.

**Electric Light in Churches.**—Arrangements for the complete lighting of the Church of St. Jude, South Kensington, by electricity, have just been concluded between the Vicar and Churchwardens, and the House-to-House Electric Light Supply Company, Limited, of Richmond Road, West Brompton. The installation is to consist of 275 incandescent lamps of 8 candle-power, the existing gas fittings being utilised in nearly every instance for the distribution of the light. The nave, for example, will be lighted by 144 lamps; 12 lamps to each of 12 coronas. The chancel will absorb 66 lamps, 30 on two standards in front of the altar, and 36 on four standards for the choir stalls; 18 lamps will be distributed on brackets round the galleries, and 28 for the lighting of the aisles. There will be 5 lamps within and about the organ, one of them being a portable lamp, to facilitate tuning operations, &c., without the danger involved in the use of matches and of exposed gas burners. The remaining lamps go for the lighting of the vestry, gallery stairs, &c., &c. The whole installation will be completed, connections made with the company's mains, and the current supplied within about a month.

**Electric Lighting at Portsmouth.**—The new Portsmouth Town Hall, which was declared open with befitting ceremony by the Prince and Princess of Wales on Saturday, has been temporarily illuminated at night by the electric light. The Admiralty kindly placed the services of Mr. Lane, dockyard electrician, at the disposal of the corporation, and that official and his staff brought to bear on the magnificent building three search lights of 25,000 C.P. each. The general effect was heightened by some interesting experiments in colour.

**Southampton and the Electric Light.**—At a meeting of the Town Council it was resolved to refuse the offer of the local electric light company, which wanted £750 for the licence obtained from the Board of Trade.

**Electric Light at Ilkley.**—It is said that there is a probability of the town authorities adopting the electric light.

**Electric Lighting at Sydney.**—Electric light plant has been erected in the Hotel Metropole for supplying 700 incandescent lamps. The installation was designed throughout by Drake and Gorham, and the work was carried out at Sydney to their instructions and specification by Mr. J. A. Arnot, of the Union Electric Company, of Australia. The plant is considered one of the finest and most successful hitherto erected in the colonies.

**The Tory Island Signal Station.**—The *London-derry Sentinel* of the 7th inst., states that the opening of the signal station on Tory Island has been arranged to take place on the 26th inst., when the opening ceremony will be performed by her Grace the Duchess of Abercorn, who will send the first message to the Queen. The event will be made the occasion of an excursion to the island, and the steamer *Thistle*, of the Laird Line, has been secured for the trip. On arriving off Tory, the *Thistle* will sail round the island, enabling the visitors to obtain a good view of it, and off the Greenport a floating despatch-case, containing the Duchess's telegram, and those of any members of the party who may be desirous of investing a shilling for a telegram from the furthest point in the Atlantic within the area of the United Kingdom, will be dropped overboard, picked up by a boat from the island, and taken to the signal station, whence the messages will be despatched to their destinations in all parts of the kingdom. This will be the first practical experiment of Mr. McNeill's scheme for communication with passing Atlantic liners which Lloyd's Committee have adopted.

**Is it Visual Telegraphy?**—In the *Evening Standard* of the 9th inst. we read the following:—"Telegrams from the Azores state that the continued drought is causing great damage to the crops, and creating financial and commercial difficulties, in consequence of which the inhabitants are protesting against the fresh taxes recently imposed." We fail to see how a telegram can come through a cable which does not yet exist, although so frequently proposed.

**Appointment.**—We are informed that our note last week to the effect that Mr. A. R. Bennett had been appointed engineer-in-chief to the Mutual Telephone Company was, at least, premature. Mr. Bennett has resigned his post of general manager in Scotland to the National Telephone Company, but, so far, has not entered into an engagement elsewhere.

**New Primary Battery.**—A company is in process of formation to manufacture a new primary battery for telephonic purposes.

**The E.P.S. Monopoly.**—It has for some time past been rumoured in electrical circles that the monopoly held for this type of storage battery could be broken down by the expenditure of £10,000 in the law courts, and it is probable that an attempt will, at no distant date, be made to effect this object.

**Electrical Engineering in Melbourne.**—Owing to the repeated request of students, a class has been formed at the Working Men's College, Melbourne, in electrical engineering. Over 90 students have enrolled for the first term, and Mr. A. J. Arnot, M.I.E.E., late engineer in charge of the Grosvenor lighting station, has been appointed instructor.

**Cost of Arc Lamp Trimming.**—The manager of an American firm has introduced the system of paying lamp trimmers on a piece-work basis. Previously they received \$2 a day; now they are able, being paid 2 cents per lamp, to make as much as \$65 a month. Each man, on the new basis, looks after, on an average, 100 lamps a day.

**An Arc Cigar Lighter.**—An interesting novelty has been made by an American firm for cigar lighting. It consists of a small arc lamp, the mechanism of which is hidden. By pressing a button the arc is started, and the mere application of the cigar lights it uniformly. The lamp consumes only half an ampère at an E.M.F. of 50 volts. The cost, it is claimed, does not exceed 8d. a month. It can be readily transformed into a table lamp by the addition of an ornamental shade.

**The Work of Street Cars.**—Recently compiled figures show that there are in America and Canada nearly 9,000 miles of street car track. Out of this number about 6,000 miles are worked by horses, and 2,000 by electricity. This is a wonderful percentage when we consider that electric cars have only been working about five years.

**Gas Engine Wanted.**—The clerk of the Cokermonth Local Board requires an estimate for furnishing and fixing a gas engine for raising water. Particulars on application to Messrs. Pickering and Crompton, civil engineers, Whitehaven.

**Edinburgh Exhibition Awards.**—It has been decided by the Executive Council of the exhibition that no awards will be made in the electrical section.

**City and Guilds Institute.**—On referring to the advertisement, page 12 of supplement, our readers will find the programme for the session 1890-91. The entrance examinations will take place on September 22nd to 24th for the Central Institution, and on September 30th for the day department of the Technical College, Finsbury. Full particulars may be obtained at the office of the Institute.

**Electricity in Fulham.**—The vestry has refused the application of Mr. S. Morse, on behalf of the Chelsea Electricity Supply Company, for permission to run electrical trams through Fulham.

**Correction.**—In the portion of the Institution paper, "The Working Efficiency of Secondary Cells," published last week, the following corrections should be made: Page 167, first col., 5 lines from the bottom, for 0.045 ohm, read 0.0045 ohm; second col., 2nd line, for 0.11, read 0.011 ohm; 3 lines from bottom, 0.038, read 0.0038 ohm; page 168, 2nd line, first column, 0.09, read 0.009 ohm.

**German Telegraph Employés and Uniforms.**—The German Emperor has now, by a recent warrant, given a special uniform to the ladies employed by the Administration of Posts, Telegraphs, and Telephones. Henceforth these ladies will have to wear a knitted blue jersey with orange yellow collar—similar to the officers of German dragoons—with metal buttons and ornaments. The Berlinese who have seen the innovation, find the effect charming; but the unhappy young women, it appears, do not feel any goodwill for Herr von Stephan, the Postal Secretary of State, for the new attractions which he has procured for them. Probably, as everything German is just now so popular in England, from the *Pickelhaube* downwards, we shall soon have our telegraph employés put into "uniform."

**Foreign Trade.**—The exports during July of telegraphic wires and apparatus connected therewith, amounted to £56,575, as compared with £32,909 in July last year, and £21,571 in July, 1888. For the seven months ended 31st July, the figures were £778,287 in 1890, £609,365 in 1889, and £265,784 in 1888. The value of the imports of copper ore for the month was £62,702 this year, £87,530 in 1889, and £135,692 in 1888; regulus and precipitate, £347,775 this year, £312,492 in 1889, and £404,495 in 1888; while unwrought and part wrought copper amounted to £347,775, £312,492, and £404,495 respectively. The imports of caoutchouc were £159,209, £131,883, and £117,363, and of gutta-percha £43,657, £47,531, and £7,623.

**Tramway in Lombardy.**—Some time ago a project for an electric tramway between Lodi and Chignole was brought forward, but owing to the high initial expenditure required, the scheme was left in abeyance. Mr. Pietro Zoncada has revived the project and proposes to reduce the amount of capital necessary so that the tramway may be built. A company is shortly to be formed to construct the line which will be the second in Italy.

**Woodhouse and Rawson United, Limited.**—The contract department of the above firm held its annual excursion on Saturday, August 2nd, when a most enjoyable day was spent, Brighton being the scene of revelry. After dinner, everyone was pleased to hear, from the chairman, of the rapid strides the department had made during the past year and musical honours were accorded to the healths of Messrs. Reginald J. Jones and B. Thomas, their energetic engineers.

**Deeper and Deeper Still.**—A subterranean Eiffel Tower for London is the discovery of a Florentine journal, according to which, a company has been formed in London to construct a huge shaft bored to the depth of 1,500 feet, with lifts, platforms, and restaurants at various depths, and geological collections showing the points of the various strata traversed. It will be lighted by electricity, and will have "a scientific as well as a merely recreative purpose."

**Re The International Cable Company, Limited.**—Mr. Justice Stirling has fixed Thursday, the 21st inst., at 12 o'clock, at his Chambers, Royal Courts, Strand, W.C., as the time and place for the appointment of an official liquidator of the company.

**Dissolution of Partnership.**—The partnership between Messrs. Jno. Shaw, Thomas Connolly and William Speakman (Shaw & Connolly), electrical engineers at the Newton Electrical Engineering Works, Newton Heath, Manchester, has been dissolved by mutual consent from the 5th inst.

**Electric Belts.**—It is almost a hopeless job to try and educate the daily press to such a point that they will decline to insert the advertisements of the purveyors of electric belts and similar appliances, but better things are to be expected of a journal which professes to be of a quasi-scientific nature. Yet, week by week, a contemporary inserts the announcements that Harness's belt is "a safeguard against rheumatic and nervous affections, liver and kidney diseases, and ladies' ailments," and possibly, also, corns, the potato disease, cholera morbus, scarlet fever, housemaid's knee, and all the ills that flesh is heir to. We should be glad if some explanation of the circumstances were given, and to learn whether our contemporary is prepared to assert a belief in the statements put forward.

**The Edison Phonographic Toy and Automaton Company, Limited.**—The following has been issued by the secretary to applicants for shares:—"I am instructed by the Board to inform you that questions having arisen as to the ownership of certain of the patent rights proposed to be acquired by this company, the directors have decided that at present it is undesirable to make any allotment of shares. Kindly, therefore, send in the banker's receipt for the amount paid by you on application, and I will forward you cheque for the amount paid by you per return of post."

**Peculiar Accident in Edinburgh.**—On Monday night a newsboy accidentally fell from the top of an electric lamp-post at the foot of the Waverley Steps, and was picked up insensible. He was taken to the Royal Infirmary, where it was found that his skull was so severely fractured that his recovery is considered rather doubtful. By some of those who witnessed the accident it is supposed that on climbing to the top of the post—a height of about 14 feet—the boy came in contact with the electric current, and was really flung to the ground by the severity of the shock. This, at all events, is clear, that his fall broke the wire or cable, and left the entire Waverley Station in darkness, so far as the electric light was concerned. Men had to be summoned to light the station gas-lamps.

**Electric Traction.**—A minute of the Tramways Committee of the Glasgow Town Council states that a letter had been received from the Electric Tramcar Syndicate, Limited, bringing under the notice of the committee their system of electric traction. Consideration of the matter has been postponed.

**The Gaulard Monument.**—The monument recently erected at Lanzo, Italy, to M. Gaulard, by the Societa Elettricità Italiano, of Milan, was inaugurated on the 3rd of the current month.

**Fareham Electric Lighting Poles.**—The Grand Jury at Winchester Assizes returned a true bill against the Fareham Electric Light Company, the contractors, and three other persons, charging them with committing a nuisance in erecting poles. On behalf of the prosecution, application was made to Mr. Justice Mathew, in accordance with the usual practice in such cases, for an order that the case should stand over to the next Assizes, to give the defendants an opportunity of pleading to the indictment.

**Telegraphy in San Salvador.**—A Consular report states that there is now a total of 89 telegraph offices in San Salvador, with about 1,467 miles of wire. The telegraph service, in general, is satisfactory. The rate for an inland message, or one to any of the four sister republics, consisting of five words, and not including the address and name of sender, costs 1 real 12½ c., or about 4½d.

**Telephones in San Salvador.**—The same authority announces that the telephone service of San Salvador has a wire mileage to the extent of some eighty leagues, and when the lines in construction are completed, it is computed that there will then be wire employed extending to 110 leagues. Private telephones in use number 111, whilst in the Government service 48 are employed.

**Cable Testing.**—There has just come to hand a letter on this subject from Mr. H. Cuthbert Hall, which will receive the attention it deserves in our next issue.

**A Real Electrical Locomotive.**—Says the *Victorian Electrical and Telegraphic Journal*:—"The following graphic description of a locomotive charged to a high tension with electricity has been brought before our notice:—"When the engine commenced to blow off, the engine seemed to be charged with electricity to such an extent that it was as much as I could do to hold the lever, and if ever I put my hand on the iron bucket and touched the lever with the other hand, the sparks seemed to come out of the tips of my fingers. It would even give a shock *through the clothes* when in contact with the lever wheel." This last statement is, we think, slightly overdrawn, and further particulars of the thinness and texture of the interposing garments would be acceptable. The phenomenon is not novel, but any accounts from eye-witnesses would doubtless prove interesting to our readers, who may try and solve its probable cause."

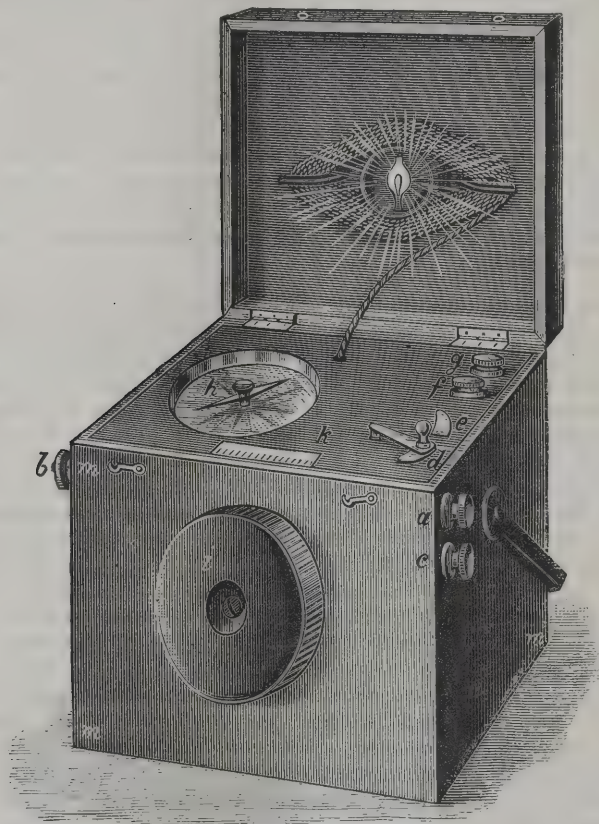

**Increasing Locomotive Traction.**—On June 16th, Mr. C. Selden, telegraph superintendent of the Balt. and Ohio R.R., read a paper before the Railway Telegraph Superintendents' Convention, Niagara Falls, on "Increasing Locomotive Traction by the use of Electricity." In this we read "efforts were made some 15 years ago, by an Englishman named Wederman, to overcome the non-adhesion by winding the spokes of the driving wheels with wire, thus making a magnet of the wheel, with the view of, by magnetism, attracting the wheel to the rail, thus increasing the friction, and thereby the adhesion to the rail of the locomotive. Having but a primary battery, the results were so slight as not to be appreciable." Mr. Selden is grievously in error; the so-called Englishman was a German named Werdermann; the wire was not wound on the spokes of the driving wheel, for the wheel was made hollow and divided into two separate halves, the wire being coiled inside on the axle; and instead of a primary battery, Mr. Werdermann used a very powerful Gramme machine. The result, however, of his experiments showed that a pull of half a ton would detach the rail from the wheel, so the idea of using magnetism to increase adhesion, to any useful extent, was abandoned.

**American Promptness.**—*Apropos* of the great fire, involving a loss of \$125,000, which took place in the Western Union Building, New York, on Friday, July 18th, *Electric Power* remarks:—"The astonishing recuperative power of American business men was never better shown than in this fire. In less than a week from the time of the fire, everything was again in perfect running order, and the immense business of the company was handled with accuracy and promptness."

**China and Japan Telegraphs.**—The Hong-Kong Chamber of Commerce, and other Chambers in China and Japan, have presented a petition to the Queen in opposition to the ratification of the pending Convention between the Chinese Government and the Eastern Telegraph Company and the Eastern Extension, Australasia and China Telegraph Company, Limited. The petition complains that the Convention has for its object the monopoly of telegraph business between China and the outer world, and that the continuance of present extreme rates for the transmission of messages must prove detrimental to commercial and other interests generally.

**The Compound Winding Case.**—The Anglo-American Brush Corporation has intimated that it will appeal to the House of Lords. What good can come out of this is better known to the Corporation than to us.

**The Central Station Companion.**—A combination instrument, called "The Central Station Companion," has just been invented by Mr. H. J. Dowsing and Mr. A. A. Day, the leading features of which are its compact form and simple arrangement, qualities which are greatly to be recommended. The "Central Station Companion," as usually made, is of the following dimensions, viz.: 6 inches by 8 inches by 4 inches, and contains:—1. An ordinary detector or galvanometer. 2. A Wheatstone bridge to measure from .05 to 50 ohms. 3. A standard ohm. 4. A variable resistance or rheostat. 5. A set of four small accumulators for giving a light when testing. 6. Necessary switches, connections, contacts, &c. If required, a 10-ohm standard coil can be inserted to increase the readings tenfold. An essential

feature of "The Central Station Companion" is its simplicity. Any workman can use it, and as there are no loose keys, complicated coils, or calculations to make, mistakes cannot occur. To use as a detector, the ends of the circuit must be connected to the two end terminals, and the key pressed, when the battery and galvanometer are put into circuit. To use the Wheatstone bridge, all that has to be done is to insert the resistance to be measured between two of the terminals and turn the knob in front (which inserts more or less resistance), while pressing keys until there is no deflection in the galvanometer. Then read the actual resistance from the scale. As above stated, there are no calculations required, and the resistance in ohms is read off direct. With a little adaptation the instrument can be used as a potentiometer, or for comparison of potentials, by Poggendorff's method. The incandescent lamp is a useful addition to the testing set, and makes the instrument useful as a portable lamp, and the battery can readily be charged at any of the stations where low tension continuous currents are in use. If, however, it is preferred, a special form of Leclanché can be fitted which will run a small lamp for a few minutes, giving ample time to make intermittent tests. It is an important point in connection with this testing apparatus that it can be made to measure higher or lower resistances as required for special purposes. The scales can be given a large range of reading at any desired point,

so that accuracy may be assured. Perhaps the greatest argument in favour of the "Companion," beyond its compactness and portability, is its low price. One of the ordinary size can be obtained at about half the cost of the cheapest form of a Wheatstone bridge.

#### NEW COMPANY REGISTERED.

**Atlas Engine Company, Limited.**—Capital £12,000, in £1 shares. Objects: To acquire as a going concern the Atlas Engine Company, at Poole, Dorset, and to carry on the business of engineers, electricians, electric light contractors, dynamo manufacturers, &c. Signatories (with 1 share each): E. Sparshott West Field, Peter Gotto, both of Poole; C. Lamb Gotto, 54, Oxford Street; J. Foster Penny, 8, Trafalgar Square, Brompton; A. Brunel Armitage, 5, New Broad Street; H. G. Gotto, 54, Oxford Street; J. Haynes, 92, Tufnell Park Road. In lieu of a board of directors, the management is vested in the two first subscribers, who are appointed managing directors, and will each be entitled to a monthly salary of £12 for the first three years, subsequently to be increased as the company in general meeting may determine. Qualification, 500 shares. Registered 9th inst. by Walter Deverell and Co., 5, New Square, Lincoln's Inn.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Electric Traction Company, Limited.**—At an extraordinary general meeting of this company, held at 35, New Broad Street, on the 1st ult., it was resolved to wind up voluntarily, Mr. G. A. Redford being appointed liquidator, with authority to dispose of the company's property to the General Electric Power and Traction Company, Limited, as agreed to by a contract of 23rd May, 1890, between this company of the first part, Moritz Immisch & Co. of the second part, and the General Electric Power and Traction Company, Limited, of the third part. The resolutions were confirmed on the 23rd ult., and were duly filed on the 6th inst.

**Mutual Telephone Company, Limited.**—The nominal capital of this company has been increased to £250,000 in £10 shares, beyond the registered capital of £100,000, in accordance with the resolution passed in general meeting on the 21st ult. The notification to the Registrar of Joint Stock Companies of such increase was filed on the 7th inst.

**Byng Telephone Company, Limited.**—At an extraordinary general meeting of this company, held at St. Nicholas Chambers, Newcastle-on-Tyne, on the 2nd ult., it was resolved to wind up voluntarily, and that Mr. John Philip Spencer, of 48, Collingwood Street, Newcastle-on-Tyne, be appointed liquidator. The resolution was confirmed on the 18th ult., and was duly filed on the 5th inst.

The annual return of the company, made up to the 30th April, was filed on the 5th May. The nominal capital is £5,000 in £10 shares; 207 shares have been taken up, and £8 per share has been called and paid thereon, the paid-up capital thus being £1,656.

**Electric Meter Company, Limited.**—The statutory return of this company, made up to the 1st inst., was filed on the 2nd inst. The nominal capital is £50,000 in £10 shares; 2,007 shares are taken up, 2,000 of which are considered as fully paid. Upon the remaining 7 shares the full amount has been called, but remains unpaid. Registered office, 25, College Hill.

**Durand Electric Petroleum Gas Engine Manufacturing Company, Limited.**—The statutory return of this company, made up to the 29th ult., was filed on the 2nd inst. The nominal capital is £100,000, in £5 shares. 1,907 shares are taken up, and of these, 1,900 are considered as fully paid. Upon seven shares the

full amount has been called, but remains unpaid. Registered office, 175, Strand.

**Crompton and Company, Limited.**—The annual return of this company, made up to the 4th inst., was filed on the 8th inst. The nominal capital is £140,000, divided into 20,000 preference, and 8,000 ordinary shares of £5 each, the whole of which are taken up. Upon 20,000 shares the full amount has been called, the calls paid amounting to £99,980, and unpaid to £20. The remaining 8,000 are considered to be fully paid.

**Elmore's Wire Manufacturing Company, Limited.**—The statutory return of this company, made up to the 28th ult., was filed on the 7th inst. The nominal capital is £300,020, divided into 150,000 ordinary and 10 founders' shares of £2 each. The shares are 64,333 ordinary and 10 founders'. Upon the former £1 per share has been called, and upon the latter the full amount. The calls paid amount to £55,641 5s., and unpaid to £8,671 15s. Registered office, 20, Bucklersbury, E.C.

## CITY NOTES, REPORTS, MEETINGS, &c.

### Maxim-Weston Electric Company, Limited.

AN extraordinary general meeting of shareholders, of whom some fifty were present, was held at Winchester House on Thursday last, when the following resolution was moved by the Chairman, Mr. J. B. Gooding, seconded by Mr. Couchman:—That it has been proved to the satisfaction of the meeting that the company cannot by reason of its liabilities continue its business, and that it is advisable to wind up the same; and, accordingly, that the company be wound up voluntarily.

The Chairman said, in his opinion, the present board of directors was not in any way responsible for the disastrous state of the company's affairs. The company had been started under very unfavourable conditions. It started with a nominal capital of some forty or fifty thousand pounds, of which only fourteen thousand was subscribed. They were acquainted with the manner in which it had been spent; the company was now practically without resources and the directors felt compelled to ask them to pass the resolution before them. A meeting had been held to ascertain the feeling of the shareholders with regard to subscribing any more money to keep the company going. Although some £1,500 pounds had been promised by way of debentures, that was not nearly sufficient to admit of the concern being carried on. Before submitting the resolution he read a few figures connected with the working of the business during the past six months. The company had on January 1st, roughly, £5,000 in hand; it had since received on account of shares £30; for transfer fees £5; bank interest on deposit £13 10s.; a loan of £50; on accounts collected and for work done £1,200, making a total of £1,303 4s. 5d., or a gross amount of £5,700. The company had paid for directors' fees £148; salaries £467; wages £336; rates and taxes and rent £220; gas account £106; travelling expenses £28 4s. 4d.; petty cash £125; trade accounts £2,255; liquidation costs and other expenses incidental to legal proceedings £970; making a total of £4,658. That left a balance of £1,031, of which £1,000 lay in the bank to the credit of the liquidators of the old company. The company's present liabilities amounted to £256; cash in hand and accounts to be collected to £74, and as assets to be received from St. Margaret's Mansions—but whether recoverable remained to be seen—£300. So that although the company's affairs were in a very bad state it would go to the wall without taking anybody there, i.e., it would discharge its liabilities. The directors had received one or two very encouraging letters from shareholders, but the result of the last meeting had been so unsatisfactory that they had thought fit to draw up the resolution which was now before the meeting. In reply to a shareholder, he further stated that the action against Mr. Watt was still pending; the solicitor thought it more than likely to be completed within the present year, after the vacations. With regard to the position of the company with reference to the liquidators of the old company, the property of the present company had not yet been assigned to it by the old liquidators. The present position was this: any assets realised by the sale of the company's property, would, the directors had been informed by the solicitor, be required by the liquidators of the old company to be deposited at the bank pending Mr. Watt's action. He, the chairman, could not altogether reconcile that with the statements and actions of the old liquidators in the past. The directors were told in the first instance that £1,000 would cover everything, next that £2,000 was required, and now they were told that a liquidator of the new company selling any of the company's effects would be unable to touch one farthing of the proceeds. So the company was practically at the mercy of the liquidators of the old company, and he, the speaker, could not congratulate the shareholders on occupying that position. He for one did not feel at all comfortable.

A Shareholder: Who is responsible for that state of affairs.

The Chairman: I should say the solicitors of the present company, because they did not require the old liquidators to assign.

The Solicitor: That is not the fact. This company has everything it is entitled to. What is there that it has not had beyond some four or five thousand pounds that can be realised by selling the company's effects? The chairman altogether fails to recognise that the interests of the old liquidators and of the present company are identical. Anything they may recover will be for this company's benefit; but very naturally they say "We are making ourselves personally responsible for costs and liabilities, and therefore the new company must indemnify us in case we lose." Is not that right and proper?

Several Shareholders: Yes.

The Chairman: I certainly think the solicitors should, in the interest of the present shareholders, have seen that the property was legally assigned.

A Shareholder: Surely when the new company was formed, its relation to the liquidators of the old company was defined by some contract or agreement, and surely the directors of the new company would have seen that that contract was so framed as not to place them entirely at the mercy of the old liquidators.

The Chairman: Some months ago I called attention to the fact that the liquidators declined to convey the property of the company. I now believe that this was through an oversight on their part. But I say in the interests of this company the solicitors should have seen that the property was actually assigned. Your liquidators cannot touch one farthing of the assets as matters stand. The identity of interest spoken of by the solicitor is only apparent. We have ceased to require the services of the old liquidators, and, speaking as a shareholder, I am not satisfied to let them have their own way. With one exception, I have no confidence in them at all.

The same Shareholder: When the new company was formed there must have been as part of the reconstruction scheme, a contract that the liquidators should on some terms or other convey the property to the new company.

The Solicitor: There was a contract to convey subject to the liquidators' claim to be indemnified for any responsibility incurred by them. Why should they have taken upon themselves these liabilities for the benefit of the new company without an indemnity. I repeat their interests and yours are identical, and I am astonished at what has fallen from the chairman. It is not true that I have not called the attention of this company to the fact that, as yet, there has been no assignment.

The same Shareholder: If there was no proper contract of a kind to prevent the new company from being placed entirely at the mercy of the old liquidators, some one ought to be held responsible. If you pass this resolution you should be careful whom you appoint as liquidator.

The Chairman: the solicitor says this contract to assign exists under certain conditions. We say we have fulfilled those conditions. Now the solicitor tells us that, no matter what may be sold, the liquidators will not allow one penny to go out until Watt's action is decided. Therefore, pending that decision, we have nothing. The solicitor of the company should have insisted on the property of the old company being conveyed to us. In reply to a shareholder, the chairman said that they would have a larger sum to pay for legal expenses than the sum mentioned above, before the affair was concluded. He also said the company had had to abandon its contracts owing to want of ready money. The directors might have obtained credit, but had not seen their way to incur fresh liabilities. The company had just sufficient to pay its present debts.

Mr. Marks: I am surprised to hear the chairman say that the old liquidators will not consent to see a sixpence worth of the company's property parted with unless the funds pass through their hands. The liquidators were called upon by the shareholders to prosecute the action against Mr. Watt. It makes no difference to the company whether the property has or has not been assigned. The liquidators of the old company made an agreement with the new company, by which the new company undertook to indemnify the liquidators for any costs incurred in the action against Watt, and the assets of the old company, and also of the new company, were made liable for any sums paid by the liquidators in the action. The property has not been assigned simply because there was no need; but had they done so, the liquidators would have taken care that the new company deposited such a sum as would cover any costs incurred in the action. As one of them, I have no objection to the assignment. (To the solicitor): You would be satisfied to advise the liquidators that they would be perfectly secure if £1,000 were placed to their credit?

The solicitor assented.

The Chairman: At the last meeting of the board, the solicitor said that no matter what the present company or its liquidators might sell, the old liquidators would not allow any of the money to be spent.

The Solicitor: What I said was, that the liquidators would naturally require the liquidators of this company to indemnify them in the action against Watt.

Mr. Marks: We are prepared at this moment to execute the assignment subject to something further being placed to our credit.

Mr. Hodgson, a director: The dynamos we possess are very good of their kind, but an electrical company to succeed must progress, instead of like their late managers being content to consider themselves the best electrical company in the world and allowing some of the patents to lapse. The company has still a

very fine plant, and with proper prudence we might yet undertake small installations, only the money we have obtained has been so insufficient as to oblige us to go into liquidation. The dynamos are worth a thousand or two.

The Chairman: You will receive not one farthing if this company goes into liquidation. To carry on the works you require a capital of £100,000 at least. By confining your operations to lighting and private installations there is, I think, still a legitimate business to be done with a small capital.

A Shareholder: Whatever liabilities this company may incur we have sufficient assets to liquidate them?

The Chairman: Most certainly.

Mr. Marks: Your liabilities amount to about £300.

The Chairman: Yes.

Mr. Marks: And you estimate the value of the plant at your works at about £7,000 as a going concern?

The Chairman: Yes.

Mr. Marks: Don't you think the sense of the meeting ought to be taken as to reconstruction? No doubt there is a gigantic field of work open to competition for a considerable time.

A Shareholder: We have let everything go to the wall.

The Chairman: I am willing to admit that as much has not been done as ought to have been. But we have been employing travellers; and we have erected a private installation in Ireland which is giving satisfaction and is a splendid advertisement. But we have no capital to go on with.

A Shareholder: I do not see that it has been satisfactorily proved that we cannot continue our business. You say you have no liabilities beyond £300 except Watt's action, and you say you have £7,000 worth of plant.

The Chairman: I cannot conceal the fact that each one of the directors has already lent money to enable the company to pay its weekly wages. It is true we have been repaid but in a very haphazard manner. No doubt in the coming winter an enormous amount of lighting will be done.

A Shareholder: Is it not true that some important contracts have been lost by us simply because it was expected the company would come to grief? The Aquarium for instance?

The Chairman: The Aquarium is still open. The step which is embodied in the resolution now before you has not been taken hurriedly or rashly. We called a private meeting of shareholders but they never came.

A Shareholder: I have heard a rumour that if the meeting does not come to any resolution to-day, a petition for winding up the company will be presented to the Court to-morrow.

Mr. Hodgson: If we had £3,000 we could do a lot of work and I would personally see that the money was not wasted.

The Chairman: I have always said that the works were a clog upon our action, having no capital.

Mr. Marks: I beg to move an amendment that this meeting adjourn for a fortnight, and that in the meantime the board invite a certain number of the largest shareholders to confer as to a basis for a reconstruction scheme. I know as a fact the company has lost a good many lighting contracts owing to its not being in a position to take them in hand, the Royal Military Exhibition at Chelsea, the Waterloo Panorama, for instance. But you have laid foundations for securing many such contracts in the future, and I cannot help thinking that if the shareholders are invited to find funds for a solid reconstruction scheme, you would yet have a future before you.

The Chairman: Gentlemen who support the amendment should hand over their cheques for a sufficient sum to meet our present liabilities, viz., £300, or we shall be served with writs, and petitions will be filed.

A Shareholder: I cannot see how you are going to induce shareholders to find fresh money. £14,000 has already been frittered away at the rate of £1,000 a month and no trading has been done for it. I am prepared to support a scheme for reconstruction if Mr. Marks will consent to become liquidator, associating himself with Messrs. Hodgson and Couchman.

The resolution to voluntarily wind up the company was then put and carried.

An attempt was made, and failed, to bring in an outsider, Mr. Newson Smith, as liquidator, and Messrs. Marks and Hodgson were ultimately appointed. The proceedings then terminated.

### The City and South London Railway Company.

THE directors' report was laid before the shareholders in meeting at Winchester House, on the 12th inst. at noon, Mr. J. Grey-Mott presiding.

The Chairman said they would recollect that at the time of their last meeting the Stockwell Tunnel was incomplete, but was being steadily driven through a strata of wet gravel. That had now been completed without any mishap, and since the whole of the tunnels were now finished, the shareholders might accord their best thanks to the engineers and contractors for the exceptionally successful way in which they had carried out a work of exceptional difficulty. He believed there was hardly a record anywhere of so long a tunnel being driven with so little loss of life or accident. The completion of the tunnel had been followed by the completion of the permanent way through it; the electrical main cable had also been completed in both tunnels, as also the service of the conductor, by which electricity was conveyed to the locomotives. The lifts had taken a much longer time to construct than had been anticipated, by Sir William Armstrong's firm, and this had

necessarily caused some delay in the final completion of many of the works connected with the stations and approaches. They were now, however, making very satisfactory progress. The underground stations were practically all completed, and those above ground were very nearly so. Arrangements for lighting them electrically with light taken from the ordinary conductors used for lighting the town had been temporarily abandoned, it having been found that taking the light in that way would involve certain fluctuations, and also it would consume a considerable amount of power which the directors were unwilling for the moment to take from the general propelling power. They had, therefore, thought best to make provisional arrangements for lighting the stations with gas. These and also the signalling arrangements were nearly complete. At the depot there were three hydraulic engines for compressing the water by which the lifts would be worked; they had been tested, as also had been the pipes and accumulators, and were in good working order. There were three very powerful vertical engines for driving the electrical current dynamos; one of them had already been worked with one dynamo with very satisfactory results, and the second vertical engine and dynamo would, he believed, be worked for the first time that day. The third, which was held in reserve, was also completed, or nearly so, and he believed that in the course of the next two or three weeks the whole of the electrical plant would be in working order. The engine and carriage sheds had been roofed in, and were in other respects ready for use. So that the shareholders would see that the great bulk of the work had been completed. A great deal of the rolling stock was ready; some engines were on the spot, and, he was happy to say, the engines and carriages had been run the whole length of the line with electrical power at a greater speed than was actually required for the service of the line. They had therefore no cause to doubt that in a very short time the railway would be open, and, as regards the working, they had every reason, judging by the experimental trials which had taken place, to anticipate that there would be no difficulty on that score. The directors were now making arrangements for a working staff, and, of course, being perfectly new, it would be necessary that the staff should be given an opportunity to become acquainted with their duties, and therefore the line would be worked for a short time before being thrown open to the public, and, in fact, the engine-drivers were already practising their duties. Thus the risk of failure afterwards would be avoided. He would be very sorry to commit himself to a date after the delay which had already taken place, and he would therefore only express the hope that by the end of next month the line would be in a condition to be opened. The Bill for extending it to Clapham had received the royal assent and the name of the company had been changed to that of the City and South London Railway Company. The directors proposed at a special meeting, following the practice of all railway companies, to create the capital authorised by the Act, but they had no intention to make the extension until the line should be in proper working order. Referring to the Central London Railway Bill, he said that it had somewhat departed from the principles upon which they of the City and South of London had been working. Its proposal for a junction between the two lines would have been practically unworkable, and had been ultimately withdrawn. The Bill had now, after long enquiry, been thrown out, and he, the Chairman, was inclined to think the decision of the Lords a wise one, because the Bill had not been conceived upon the lines of the City and South London Company, nor, in his opinion, upon lines which would have made it a profitable undertaking. Possibly it would be reintroduced in an improved form, and, in that case the City and South London Company would be happy to co-operate in any workable scheme. In the meantime, many points would have to be considered in regard to any proposed extension by which the company might obtain a more complete control of the city traffic than it already possessed. That might be done at comparatively small cost. Up to the present the company had only spent some £860,000, which was very close to the original estimate. Upon that policy the future earnings and dividends of their company, and of other city underground railways, must depend, because when they exceeded beyond a certain sum, it became practically impossible for a line of railway to earn a really good dividend whatever might be the traffic; it being all essential that the capital cost should be kept within a defined and known limit. They saw what a very poor return the Metropolitan and Metropolitan District Railways gave for their enormous traffic. It was a warning which ought never to be forgotten in any extensions they might make. He begged to move the adoption of the report.

Mr. Hanbury seconded, and the resolution was agreed to unanimously.

At an extraordinary meeting held immediately afterwards, the Chairman moved to convert the share capital into stock to facilitate its transfer. He added that it was not proposed to carry it into effect immediately, or before the share capital had been more completely issued. As a rule all railway companies found it more convenient to have the capital in the form of consolidated stock. The resolution was seconded by Mr. Hanbury and agreed to, and the proceedings terminated with a vote of thanks to the chair.

### The Chili Telephone Company, Limited.

THE directors' report (printed in our issue of August 1st), and the accounts for the half-year ended March 31st, were presented at the annual general meeting of the shareholders at Winchester House, noon, August 8th, Colonel Raynsford Jackson presiding.

The Chairman said the shareholders, who had doubtless read in the prospectus that the directors anticipated a dividend from the very commencement of 6 per cent., would be inclined to ask how it happened that the report only mentioned one of 5 per cent. In the first place, when the prospectus was issued, the rate of exchange was 26d. per dollar, whereas it was now fallen to 24d., and the average rate of exchange during the eleven months over which the accounts extended had been 25½d. Had it continued all through at 26d., the company's earnings would have been between £900 and £1,000 more, and the dividend anticipated would have been realised. The directors had had still another difficulty to contend with, one which had deprived the company's general manager in Chili of the control of the company's affairs up to the middle of the last month of its financial year. It happened in this way: There was an unregistered body of shareholders in the West Coast Telephone Company residing in Chili, who, through not having had their shares registered, had been left in ignorance of the affairs of the West Coast Company until they suddenly learned that their property had been sold. They imagined that the sale price was over and above the amount of the West Coast Company's liabilities, and, therefore, that they were entitled to be paid a very large sum of money. They were entirely mistaken, because the West Coast Company's system had been purchased on the understanding that that company met its liabilities, and therefore all that these shareholders were interested in was the surplus left to the company after meeting its liabilities, which proved to be a very small sum indeed as compared to their anticipations. They thought to protect their interests by preventing, pending satisfaction of their claims, the legal registration of the transfer of the West Coast Company's system to the Chili Company, by means of an injunction obtained in the local court. The consequence was that the management of the Chili Telephone Company remained in the hands of the vending company until the middle of April, when arrangements were made for the appointment by the West Coast Company of the Chili Company's manager as their manager also. Thus the company's manager had now a recognised position which enabled him to look after the company's affairs, introduce economy, improve the service, and otherwise develop and promote the company's interests. In spite of these difficulties the company's progress had been satisfactory. An increase had taken place during the year of 33 per cent. in the number of subscribers, and in the gross revenue of the company; and he thought a still larger increase might be anticipated for the present year, not merely because the difficulties above-mentioned no longer existed, but also because the company had purchased for £36,000 the National Telephone Company of Chili, the only rival it had in the country. That company had possessed important local influence. It was formerly controlled by natives who enjoyed considerable power and influence in Santiago and Valparaiso, and who had shown themselves very hostile to the Chili Telephone Company, and had co-operated with the dissident shareholders of the West Coast Company in doing the company considerable damage. Having bought off the opposition of the National Telephone Company of Chili, the company had also weakened the position of the dissident shareholders; and he thought he might now hold out an assured prospect of its anticipations being realised, and of the shareholders possessing a property of real intrinsic and sound value. He moved the adoption of the report and accounts.

Mr. T. Greenwood seconded, and the motion was carried unanimously.

The Chairman also moved to declare a dividend of 2s. 6d. per share, as recommended, payable at the company's bankers on and after the 9th inst., free of income tax.

The Hon. F. E. Allsopp seconded, and the motion was carried unanimously.

The Chairman, in moving the re-election of Mr. T. Greenwood as director, spoke in warm terms of the services of that gentleman in connection with the negotiations referred to above. The motion was seconded by Mr. Venables, and agreed to.

The Hon. F. E. Allsopp was also re-elected a director, Mr. T. A. Welton was re-appointed auditor, and with a vote of thanks to the chair the proceedings terminated.

### Liverpool Overhead Railway Company.

THE fourth half-yearly meeting of the shareholders of this company was held recently in Liverpool. Sir Wm. B. Forwood, the chairman, presided. The report of the directors stated that the progress in the construction of the railway during the past half-year had not been as great as they had looked for. Difficulties of a technical character had arisen, but these had been surmounted, and already several complete spans were in position, and the directors had every reason to believe that henceforward the erection will proceed with rapidity. The expenses of administration had been defrayed out of interest on capital paid up, and the balance of revenue account had increased to £1,129 0s. 5d. The general balance-sheet, made up to June 30th last, showed on the debit side the following items:—Balance at credit of capital account, £105,223 1s. 7d.; balance at credit of revenue account, £1,129 0s. 5d.; amount retained as security for completion of contract No. 1, £1,295 7s. 9d.; owing to sundry creditors, £547 19s. 1d.; total, £108,195 8s. 10d. The amounts on the credit side were £5,427 17s. 5d., deposit £102,767 11s. 5d.; total, £108,195 8s. 10d.

The Chairman explained the position of the undertaking. The works were not actually commenced till October last, and the progress made had not been so rapid as the contractors had led them

to expect. This did not arise out of any difficulty in the construction of the overhead railway itself, that being a very simple matter indeed; but it arose from the automatic machinery which the contractors employed with the view to economy not being in the perfect working order which he had believed. He was glad to say, however, that all the difficulties connected therewith had since been overcome, and the machinery for turning out and drilling the plates was now working perfectly, and the work was being proceeded with as quickly as might be expected. They were now turning out nearly two spans per day, and, if they continued at this rate, the line would be completed in 12 or 13 months. Difficulties were, however, always incidental to works where machinery was employed, and therefore they must not be too sanguine that the work would be finished in the time named. It would be seen from the photographs exhibited in the meeting room that the railway, when completed, would not be an unsightly object. Indeed, comparing it with what he had seen of American overhead railways, this would be the best looking overhead railway he had seen. As to the equipment of the line, they had not yet taken any steps, but, as previously indicated to the shareholders, electricity had been adopted as the propelling power. The progress in this as a motor was such that they had been advised by their engineer to postpone deciding upon the precise system until the last moment. Referring to the £108,195 to their credit in the general balance-sheet, he was glad to say that it was gaining interest, and they would also be glad to see that after paying the expenses of administration for the past half-year, the balance to their credit on revenue account had increased to £1,129 0s. 5d. The Mersey Docks and Harbour Board had agreed to spend a further large sum at the north end in addition to what they had expended at the south. This would considerably increase the amount of traffic upon the railway. From everything he could see they would have a large traffic, and he looked forward to the future with very great expectation. He moved the adoption of the report and balance-sheet.

Mr. Richard Hobson seconded the motion, which was carried unanimously.

A vote of thanks to the chairman terminated the proceedings.

**Birmingham Tramway Company.**—At the annual meeting of the Birmingham Tramway Company, on Wednesday, the chairman (Mr. Smith) expressed the hope that they had seen an end of the fuel boom. They were paying 17s. per ton this year for what they paid 10s. 5d. for in 1887. Nevertheless, the year's operations had been very prosperous. The opening of the electric line in the Bristol Road had been demonstrated to be a scientific and mechanical success. What now remained was to see whether it could be worked with economy. Steam traction cost 3d. per mile; he believed the cost of electric traction would not be far from that sum.

**Sheffield Telephone Exchange and Electric Light Company, Limited.**—It has been resolved to wind up the company voluntarily in view of a reconstruction. Messrs. T. G. Shuttleworth, accountant, and W. Johnson, the secretary of the company, both of Sheffield, are the liquidators, with power to consent to the registration of a new company, to be named "The Sheffield Telephone Exchange and Electric Light Company, Limited," and to make an agreement with such new company.

**The European Electric Welding Company.**—A further payment of £20,000 has been made in Boston by the English purchasers of the company, making £70,000 paid in cash. Payment of the balance, £40,000 and 33½ per cent. of the stock to be issued by the London company, is guaranteed by the City of London Contract Company, the cash to be paid about November 1st.

**The Schanschieff Electric Battery Syndicate, Limited.**—Creditors are further notified to send names and addresses and particulars of debts and claims to Richard Rabbidge, the liquidator, 32, Poultry, London, E.C., on or before the 19th instant, or to be excluded from any distribution prior to such claims.

**Elmore's Wire Manufacturing Company, Limited.**—Application has been made to the Stock Exchange Committee to appoint a settling day, and grant a quotation in respect of ordinary shares.

**The Electric Construction Corporation, Limited.**—Application has been made to the Stock Exchange Committee to allow the company's shares to be quoted on the official list.

### TRAFFIC RECEIPTS.

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending August 8th, were £4,863.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending August 8th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,761.

## THE RIES ELECTRIC TRACTION-INCREASING SYSTEM.

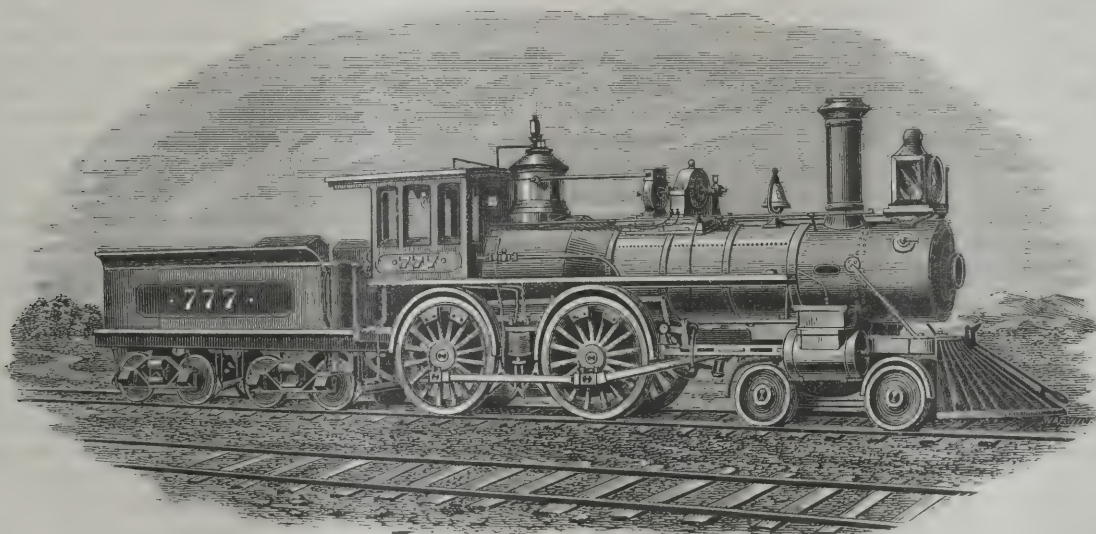

WE have recently devoted considerable space to the discussion of the increased adhesive effect produced between driving wheels and rails and other metallic surfaces when traversed by an electric current under given conditions. Among the contributions upon this interesting subject, we (*New York Electrical Engineer*) have had the pleasure of describing in detail the important results obtained by Mr. Elias E. Ries, during a series of original investigations and experiments extending over a considerable period, in the direction of applying this method of increasing tractive adhesion to steam and electric railway locomotives.

It will be remembered that in this system of electrically increasing traction as developed and practiced by Mr. Ries, a low tension quantity current is made to flow through a local circuit of almost negligible resistance, of which circuit the driving wheels and that portion of the track rails immediately below and between them form the principal part. This current produces a slight local heating or incipient welding

we understand are now in progress on the Baltimore and Ohio Railroad.

Referring to our illustration, it will be seen that the traction-increasing current is generated by a small alternating current dynamo driven by a rotary engine supplied with steam from the locomotive boiler. The engine and dynamo are mounted upon a common base secured to the boiler in the position formerly occupied by the sand box. One or both pairs of driving wheels are electrically insulated from the body of the locomotive and from each other by the use of special insulation surrounding the driving box and side rod brasses. The insulation so far employed has proven itself fully capable of withstanding the exceptionally severe strain to which it is subjected, and tests made after several months of continuous service have led to its permanent adoption for this class of work.

Electrical connection with the two pairs of drivers is maintained by means of peculiarly constructed brushes bearing upon brass sleeves secured to the central portion of each driving axle. These brushes are connected, by means of heavy stranded copper conductors, with the source of low tension current, which in the case illustrated is a transformer (not shown) placed in proximity to the main driving axle. A type of machine is now about to be used, however, which generates

effect at the points of contact between the wheels and rails, which is practically instantaneous in its action, and brings about a decided increase in the coefficient of friction between the opposing metallic surfaces.

Practical interest in the subject has recently been awakened among railway men by the exhibition of working models of this invention at the annual meetings of the Association of Railway Telegraph Superintendents, and of the American Railway Master Mechanics Association, held at Niagara Falls, N.Y., and at Old Point Comfort, Va., respectively, on June 18th and 19th, 1890, at which the new method of increasing tractive adhesion met with considerable favour, the models exhibited showing an increase in traction due to the current of over 200 per cent. Preliminary tests of the invention, as applied to steam locomotives in regular service, have been very successful, and this, together with the favourable reports of experienced railroad officials who have investigated the system, has recently led to the organisation, in Baltimore, Md., of the Ries Electric Traction and Brake Company, with a capital stock of \$2,000,000, for the purpose of further developing and introducing the same.

We are enabled this week to present to our readers, through the kindness of this company, a perspective view showing the general appearance of a steam passenger locomotive equipped with their electric traction-increasing apparatus, and we hope soon to be able to make public the results of the new series of test that

directly the low tension quantity currents required. As the resistance of the traction-increasing circuit is practically constant under given track conditions, the flow of current is usually regulated by varying the electromotive force, which, on account of the low resistance of the circuit and multiple connection of the driving wheels, can be kept very low. The current density at the points of contact between the driving wheels and rails can be varied at will, according to the percentage of increased adhesion desired, the usual range being from 500 to 2,500 amperes.

It is proposed to use part of the current generated by the dynamo, either directly or indirectly, according to the type of machine employed, for the operation of electric locomotive and train brakes, electric headlight and train lighting, &c., in addition to its use for increasing traction. The dynamo is generally kept running at a slow rate of speed when not otherwise employed, and is so constructed as to respond promptly and automatically to any demand that may be made upon it within the limits of its capacity.

Experiments already made upon a large scale have shown that by this method it is possible to increase the tractive adhesion of locomotives fully 25 per cent., thus enabling them, with a saving of fuel, to haul a largely increased load, to mount heavier grades, and to descend the same under perfect control and without the skidding of wheels. Besides this, it will enable railroads to haul, with their present engines, much longer trains

than they can now do, thus not only increasing the carrying capacity of the road, but saving largely the wear and tear upon tracks and bridges that the use of heavier engines for this purpose would entail. It will likewise enable both passenger and freight locomotives to make better speed and to maintain schedule time notwithstanding ordinary unfavourable conditions of the track due to the weather.

A recent report of a large railway shows that an increase of *one-fifth of one car* per train brought an increased revenue of over \$50,000 in six months. It is needless to say, therefore, that if the claims made by the Ries Electric Traction and Brake Company for their traction-increasing system are even partially realised in practice—and the experiments already made by Mr. Ries go to indicate that these claims are entirely within the mark—the increased earnings to railroads from the use of this invention would be simply enormous, to say nothing of the operating and other advantages to both steam and electric railways that would result from its adoption.

## PARLIAMENTARY NOTES.

### THE DUBLIN SCIENCE AND ART BUILDINGS.

IN the House of Commons last Thursday night, in answer to Mr. P. O'Brien,

Mr. JACKSON said: Four firms were invited to tender for lighting the New Science and Art Buildings in Dublin by electricity, viz., Messrs. Siemens Brothers and Co., Messrs. Johnson & Phillips, Messrs. Edmundson & Co., and the Brush Company, and tenders were received from the three first named. Messrs. Edmundson's tender for £8,375, being the lowest, was accepted; the contract with them contains no stipulation as to giving a preference to any firm.

### USE OF TELEGRAPHS BY THE FISHERY BOARD.

During the debate on Supply last week, Mr. DUFF, in the course of a speech, complained of the action of the Fishery Board in taking from the surplus herring brand fees £1,500 for the extension of telegraphs. He did not deny that the telegraphs were of great importance to the fishing community, but he contended that they were used for Imperial purposes.

The LORD ADVOCATE in his reply stated that the application of the money of the fund to telegraphs had been described as a grant in aid of the Imperial expenditure, but he would point out that it was not a correct way of describing it, because it was merely aid given to the fishing harbours for telegraphic purposes.

### DIRECTORS' LIABILITY BILL.

In the House of Lords, on Friday night, Lord HERSCHELL, in moving the third reading of the Directors' Liability Bill, explained and vindicated the alterations made in the measure by the Standing Committee of their lordships' House, contending that, instead of weakening and maiming the Bill, as some critics had alleged, they only tended to render it more easily workable and effective. He, however, expressed his regret at the adoption in committee of the whole House of the Lord Chancellor's amendment in respect to responsibility for the statements of experts—a change which, he thought, involved considerable danger.

The Lord CHANCELLOR defended his action in regard to the Bill, asserting that his only object had been to make it, if possible, a reasonable and workable measure.

After some remarks from Lord BRAMWELL, the Bill was read a third time, and, having then undergone some verbal amendment, it was passed.

### LIGHTHOUSE ILLUMINANTS.

In the House of Commons, last Friday, Mr. T. W. RUSSELL asked the President of the Board of Trade whether the committee of the Royal Society appointed to inquire into the report on lighthouse illuminants

had sent in their report, and, if not, when it might be expected.

Sir M. HICKS-BEACH: I understand from the president of the Royal Society that the committee on this subject do not propose to have any further interviews, and that their report is partly drawn up, but it seems doubtful whether it will be finished before the prorogation.

### THE LIGHTING OF THE HOUSE OF COMMONS.

Sir G. CAMPBELL asked the First Commissioner of Works if he would arrange before next session to put shaded electric lights in the roof of the House, so as to save members from the heat and glare of the gas in the long winter nights, and make the nearest possible approach to daylight.

Sir H. MAXWELL said the electric light was tried some time ago in the roof of the House, but the results were not satisfactory. The present gaslights were connected with the ventilation, and it would be inconvenient to dispense with them.

### TELEGRAPH CLERKS.

Dr. FARQUHARSON asked the Postmaster-General whether any steps were being taken to redress the grievances complained of by the clerks of the Central Telegraph Office as to the extra hours without equitable remuneration for what are known as long and short duties.

Sir H. MAXWELL (on behalf of Mr. Raikes): In reply to the hon. member, I have to state that much attention has been given to the duties referred to, with every desire to lighten their incidence, but no one, either on the part of the Post Office or on the part of the officers themselves, has been able to suggest any practicable scheme for getting rid of these duties. This matter formed an element of consideration in improving the pay under the scheme recently issued.

### DUBLIN TELEGRAPH DEPARTMENT.

In answer to Mr. MacNeill,

Sir H. J. MAXWELL said: The question of revising the salaries of the Dublin supervising staff will be considered as early as possible in connection with similar questions elsewhere, but it is improbable that improvement, should improvement prove to be necessary, will take effect from a date anterior to that on which the authority of the Treasury is given.

## THUNDERSTORMS.

A TYPICAL thunderstorm, writes Mr. H. A. Hazen in *Science*, is first seen as a dense, ragged cloud in the west, extending to a height of over a mile. The sky is entirely clear elsewhere, except sometimes covered by a light fleecy veil of cirrus. The cloud in the west rapidly enlarges, and completely covers the sky except a small portion to the east and south-east. The motion of these clouds is distinctly from the west and quite rapid, while the surface wind is from the south and quite gentle. This wind is blowing toward a general storm situated about 500 miles to the north-west, and has no connection at all with the thunderstorm, which is suddenly, interjected, as it were, upon the quiet air. Often there are seen two clouds in the south-west and north-west which seem to meet together and produce the storm, but more often the first appearance is that of a great cloud of dust borne upward about 300 feet, and advancing with great rapidity from the west (sometimes 80 miles per hour). Some of the clouds sprinkle a little rain as the dust-cloud advances, but this is very light. When the storm is very severe, a loud roar is heard like the continuous discharge of electricity, which produces a steady instead of intermittent thunder. During this time, lightning-flashes are seen and distant thunder heard. In a few moments, after the dust-cloud has approached nearer, and practically with it,

the wind suddenly whirls to the west, and blows with great velocity (sometimes 80 miles per hour). Then, in a moment or two more, the lightning and thunder become very intense, and rain falls in torrents. Often the lightning's flash is the signal for a fresh downpour, allowing a few seconds for the fall of the rain from its height. This phenomenon has led to the view, now almost universally accepted, that there is a most intimate relation of cause and effect in this display of electricity and the subsequent rain. Under some circumstances, but invariably in connection with this heavy rain, there fall hail-stones variously measured from the size of a pea to that of hen's eggs, and even larger. In some cases, larger masses, even as great as an elephant, have been reported, but these are due to a mingling or freezing together of many stones in the air or after they reach the earth.

During the progress of a thunderstorm, and after its front has reached the observer, there is a remarkable cooling of the air. This cooling seems to arise from a downward current in the centre of the storm. It cannot be due to the onrush of a north-westerly wind, for that must come from a warm region, since the thunderstorm has been suddenly interjected into a region of warm southerly winds flowing for hundreds of miles toward the north. This cooling is often very great, and seems to indicate that the air in the centre of the storm is not abnormally heated, as in the case of a general storm, but is very much cooled. The bearing of this upon the generation of the thunderstorm is of great importance, and does not seem to have been sufficiently considered.

When the storm passes to the north or south of the observer, there is quite a brisk breeze from it, showing that the motion of the air is from it on at least three sides. Often it is possible to view the storm, in its onward progress, with clear sky overhead, if its border does not reach the zenith of the observer. Under these circumstances, one sees very distinctly up to the highest clouds a steady motion to the east. The rain is seen falling in great sheets, and its front is very distinctly marked. This rain front seems to be an important phenomenon, and has been seen scores of times advancing with a slight lagging at the earth and in the clouds. The appearance impresses one at once as caused by a rapid motion in the middle cloud region, with a lagging at the earth possibly from friction, and in the upper part of the cloud from a less velocity at that point. In no instance has there ever been observed an uprush of air anywhere in this region. These storms go in parallel lines, and as many as four have been seen running one behind the other, the most northerly one in advance. Often it is reported that a storm has gone slightly north of a station, and then turned and come back directly over it; but this is probably an illusion. The second storm has a motion the same as the first, but goes a little farther south. The motion across the country of these storms is about double that of the attending general storm to the north-west.

Probably the most marked characteristic of a thunderstorm, however, is a rise in pressure at its centre. This rise is universally conceded to-day, though its cause is in grave doubt. It has been repeatedly observed in storms where there has been no rain, and hence cannot be due to the cooling of the air by the rain, or to its downward pressure as it falls. How is it possible to account for this rise of pressure in a storm which is itself travelling more than a mile a minute? We have here to consider a phenomenon entirely distinct from a sand-whirl of the desert, which has only a slight progressive motion. There seems to be no doubt whatever that we are to consider here a cause or a condition which is inherent in the storm itself. There can be no upsetting of the equilibrium, no uprush of air just in front of a thunderstorm and nowhere else, which could give such a rise of pressure in so rapidly a moving body of air. We are certainly dealing here with a *plenum* which moves with the storm, and, in fact, is the storm itself. It may not be that this is due to a downrush of air particles from some height; but there is no serious difficulty in assuming that, through

electrical action, there is an increased pressure in the centre. It is plain that the foregoing description has a most marked parallelism with that already given of the tornado, and it is virtually admitted that a tornado is simply an extreme development of a thunderstorm.

The attempt to show that while these phenomena are alike in most respects, and yet that in one of the more important factors they are entirely distinct, is most remarkable. We are taught that the origin of both is an unstable equilibrium, in both there is an uprush of air, in both there is a cloud of dust, in both there appear to be two clouds meeting from the north-west and south-west, in both there is a loud roar heard oftentimes, and in both there is a pronounced cooling. They are exactly alike, and produced the same way, but the final result of these actions is to develop two entirely dissimilar and almost opposite conditions. We are told that in a thunderstorm the air starts upward in the centre, has its moisture condensed by expansion, and the resulting precipitation cools the air, increases its density, and finally the diminished pressure at starting gives way to an increased pressure from this change in the density. It must be admitted that this is a reasonable conception, and may be true; but would not this at once destroy the ascending current, and bring the whole action to a standstill? Can we for a moment have both uprushing currents in a storm centre feeding its energy, side by side, with downrushing currents increasing the pressure? It is only necessary to state this contradiction in order to show the absurdity of the hypothesis. This theory strikes at the root of the whole process of liberation of energy in a moist ascending current; but more than that, if there is such a cooling and subsequent downrush, why should it not act in precisely the same manner in a tornado? How is it possible for this same uprushing current, which starts in exactly the same way in both these conditions, to continue upward in a tornado, to gather energy as it rises, to liberate more and more latent heat, to rush faster and faster, to grow warmer and warmer, and finally to produce the violent tornado with its supposed almost perfect vacuum in the centre, where a half-mile away there is perhaps a thunderstorm causing an increase of pressure? It would seem as though there could hardly be a plainer exposition of the utter futility of all the attempts that modern theorists have made to grapple with this problem, than this latest attempt to start the thunderstorm and tornado in the same direction, and finally bring them out, from almost the same conditions, facing in opposite directions, and absolutely dissimilar in their most essential characteristic.

Is it possible for electricity to produce a sudden increase of pressure in a mass of air sufficient to violently rend asunder objects which it strikes? Oftentimes the bark of trees has been driven off; and the usual explanation of this has been, that the heat of the electricity has converted the sap into steam, and this in turn has forced off the bark. This, however, is not satisfactory, for the reason that even a dead and perfectly dry tree has been struck, and scattered over a large field. A remarkable instance of explosive action in a lightning discharge is to be found in *Nature* for May 8, 1890. A tree standing in a rather open field was struck by lightning, and its fragments strewed over two acres of ground. One solid piece, weighing  $5\frac{1}{2}$  pounds, was thrown 378 feet. Other *débris* lay 210 feet in another direction. Small pieces of riven trunk and bark were found thrown in the teeth of the wind and 180 feet from the tree. The concussion or increase of pressure smashed six fine glass window-panes in a house not far away. Another very interesting effect was noted in a house that was struck in Washington, D.C., August 23rd, 1885. In this case the lightning struck the south-west corner of the tin roof on an ell built on the south side of the house, and divided. A portion of the flash passed down an eaves-spout; and at its end, which was two or three feet above the ground, it passed through the air to the damp side of the house, knocking off the plastering on the inside. The other portion of the flash passed down between the weather-boarding and the plastering on the east side

shattered one of the upright posts, and appeared to explode off the weather-boarding toward the east, and the plastering toward the west. A woman and her two sons were apparently stunned by the effects.

While such cases have usually been regarded as "freaks" of lightning, yet it would seem that the matter has not been sufficiently studied to enable us to determine just what effect such a discharge would have upon a confined air space. It may be, the apparent bursting of a house in a tornado may be accounted for in this way. An instance has already been given at St. Louis of a rise in pressure, as shown by a barograph, and at the same time a seeming bursting of houses. Hardly a month passes that there is not some discovery regarding this extraordinary force of electricity, and surely we are not in a position to deny that it might not produce a large number of effects now observed in a tornado, such as searing of green leaves, discolouring the trunks of trees, increasing the pressure, exploding houses, depluming fowls, &c. We are told that lightning flashes are seldom seen in a funnel cloud. They have been seen there many times. Moreover, it is not at all certain that an ordinary observer would be in a condition to take particular notice of the presence of electricity in a tornado; and, again, the electricity may pass down or up the funnel without a visible flash. The presence of ozone has been often noticed in a tornado where no lightning was seen.

It has been my purpose for many years to avoid, as much as possible, all speculations in considering air motions and the causes of atmospheric phenomena. This is especially pertinent when we consider electric action in the atmosphere. It is very difficult to believe that electricity has nothing to do with our thunderstorms, and is merely a result, and never a cause. The fact that physicists have never yet been able to account for more than the smallest fraction of atmospheric electricity should lead us to greater diligence in determining its methods. We know from observation that the electric potential is enormously increased as we ascend in the atmosphere. That little or no connection between atmospheric electricity and storms has been observed by our instruments near the earth is not remarkable, since the earth and air just above it may neutralise all electric action for a hundred feet or more. Our thunderstorms seem to show an enormous storehouse of electricity at five thousand or six thousand feet above the earth; at least, electricity seems to be concentrated there over thousands of square miles during thunderstorm action. We are taught that electricity forms a sort of dual condition, or the electric field is a double one. May not this electric field draw on the sun for its energy? It is believed that light, heat, and electricity are all different manifestations of the same radiant energy. The abundant source of this energy is the sun. Why may not the sun's electricity, oftentimes observed by its direct effect on our magnetic instruments, and more often still indirectly in our auroras, be intercepted by a peculiar condition of the atmosphere or of the earth below, and thus be concentrated in particular localities? Generally this electricity passes through the air to the earth, but must we think that it always does so? May not this electric field or dual condition gradually develop in the atmosphere largely independent of the passage of air particles through wind or convection currents?

For convenience it has been generally considered that particles have a tendency to leave the positive and pass to the negative pole. For example: in the electric arc light the carbon at the negative pole is built up at the expense of the positive. The velocity of transmission of these carbon particles perhaps cannot be determined, but it must be only a very small fraction of that of electricity, 190,000 miles per second. Is there any inherent improbability in the supposition that in this dual condition in the atmosphere there is a tendency for moisture and possibly dust particles, positively electrified, to pass rather rapidly from the positive pole, or, better, positive portion of the electric field, to the

negative portion? We know from observation that during the passage of a high area or clear sky the electric potential, with very few exceptions, becomes markedly positive, while during the fall of rain it is negative. While a thunderstorm is passing, there are most violent fluctuations of the electrometer needle from negative to positive and back again, as each flash of lightning is noticed. These fluctuations of the needle are perhaps a hundred times as great as under ordinary conditions of rainfall, and take place when the flash is a mile or two away, showing a most extraordinary inductive action upon the atmosphere, and for enormous distances. We have positive evidence of such transmission of moisture particles by a force entirely distinct from heat, pressure, or any other commonly recognised meteorologic condition. It is known that the moisture in the air is one of the most constant elements we have to deal with. The temperature may rise and fall thirty or forty degrees during the day, and yet the quantity of vapour is in no wise changed. The wind, either in direction or velocity, does not change this moisture. The hiding of the sun's heat or light in no wise affects it. Changes in air-pressure produce no effect in general. As a storm approaches, however, we find a most marked increase in this moisture over thousands of square miles, and this even in a calm. As a storm passes off, the conditions are sharply reversed. The moisture becomes depleted in a most remarkable manner, as though it were actually drawn out of the atmosphere by an invisible agency.

The most remarkable example of such action was observed on December 22nd, 1889, from a third-story window of a house in Washington. It will be seen that the conditions were not favourable for observing this effect at its best. At 3.11 p.m. there were 4.09 grains per cubic foot, and for more than 24 hours previous there had been an abundance of moisture from a storm passing near by. The air was almost a calm, and continued so till nightfall. At 5.2 p.m., or 111 minutes later, there was only 1.04 grain per cubic foot, and this continued as long as observed. To any one who has made determinations of the moisture of the air, and noted its great constancy, frequently for several days, this sudden subtraction must be very extraordinary. If such changes are possible near the earth, and in the centre of a large city with houses for more than a mile on all sides, what may we not expect to take place in the free air, where there are no interferences, and where we know that such forces are acting in far greater intensity than near the earth?

Just after a thunderstorm or tornado there are torrents of rain, and in some quarters it is getting to be quite the custom to call such phenomena cloud-bursts. In these cloud-bursts almost an incalculable amount of rain falls, more than a foot having been reported at times. In one case 4 feet of hail were reported. Just how much territory is covered by such a cloud-burst cannot be told, as the data are not sufficiently numerous, but 50 or 60 square miles may be easily considered. We have already seen that the later theory, which calls for a downrush in the centre of a thunderstorm, effectually disposes of all possibility of this enormous amount of moisture rushing up in the centre and being condensed by expansion. In the case of a tornado, it is incredible that even a thousandth part of this moisture can be carried up in a funnel a few hundred feet in diameter. If we inquire what would be the effect of the ordinary condensation of such a mass of water in the air over such a limited space, we are confronted by an amount of heat set free that is simply appalling. One gallon of rainfall gives out sufficient heat to melt 45 lbs. of cast iron. A very little consideration will show us that it is absolutely impossible, even allowing a current of moist air at any conceivable velocity, for even a small fraction of rain to be precipitated out of such a current. It has already been shown that the latent heat set free would at once re-evaporate the moisture. We seem to be driven to invoke the aid of some other agent than any thus far recognised as cogent in producing our storms. Is it inconceivable that we have to deal here with a negative

electric field, which draws to itself with great velocity particles of moisture from regions perhaps for 100 miles about, when suddenly, upon a discharge of electricity, the potential upon the particles is diminished, and they unite in great abundance and form raindrops? This is a most inviting field for observation. We already have facts enough to make a plausible hypothesis, and, what is very important, we have here an unlimited amount of energy which may be called upon to produce all the effects ever observed.

It is not a little remarkable that the earlier views all ascribed tornadic action to electricity, and it would seem as though the time were not far distant when we would be forced to return to this agent for explaining the phenomena. What are needed are careful experiments in this most enchanting field of research. An attempt has been already made to test the question of the transmittal of moisture through the air by electric action. A Holtz machine was run for 15 minutes in a rather large room; and most careful measurements of the amount of moisture at the machine and at a point 20 feet away, before and after the machine was in action, showed an increase at the machine. When we consider that it was impossible to measure the moisture contents just at the plate of the machine, and also what an extremely slight charge could by any possibility enter the air from the machine, we can but be surprised that any effect at all was observed. With improved methods of observation by which the exact hygrometric state of the air can be easily and accurately determined, and with very accurate tables of reduction which we now have, all that is required is an observer for investigating these phenomena. The expense for apparatus need not be great.

SHIP LIGHTING PLANT.

DURING the visit of the members of the Institution of Electrical Engineers to Edinburgh, Dr. Walmsley read a paper on "Some Chief features, mainly Electrical, of the Edinburgh International Exhibition, 1890." In the section devoted to electric lighting, there appears the following paragraph, which, with the table mentioned, we here reproduce:—

Considering the position of the exhibition, it is but natural that most of the exhibitors of dynamos and engines should include a set of ship lighting plant amongst their other exhibits. For the convenience of those visitors who are interested in this branch of electrical work, I have embodied in Table A a few particulars of

the different combinations that are open to their inspection. In the last column I have calculated as being of some interest the number of watts available in the outer current per square foot of floor space occupied. Of course, I do not mean to imply that this is the only or even the most important thing to be considered in selecting ship lighting plant, but it is interesting as showing what can be done in this direction. In comparing these numbers the steam pressures given in another column must not be overlooked.

PROCEEDINGS OF SOCIETIES.

The Institution of Electrical Engineers.

The following discussion took place on Mr. BENNETT's paper on "Foreign Currents," read at the Edinburgh meeting.

After the CHAIRMAN had proposed a vote of thanks to Mr. Bennett for his paper,

Mr. W. H. PREECE said he had been asked to supplement the remarks that Mr. Bennett had made, as regarded foreign currents that were traced, and were found not only in arial conductors but in other conductors. The phenomena that Mr. Bennett had brought before them was, he thought, indicated in Fleming Jenkin's book on electricity, where he showed that with an insulator, in wet weather, there must be currents of polarisation, i.e., the currents passing through by leakage—the moisture from the insulator decomposes the water in its constituent elements and the formation of gas must produce these currents of polarisation. Practically these currents did not produce any serious detriment on their telegraphs. There was no doubt that the transmission of signals in wet weather was slower, more sluggish than in fine weather, due to these causes. But there were other currents found in the wires not traceable on telegraphs, but very readily perceptible on telephones. He did not know whether any one present had amused themselves, as he had done by spending a whole night in a telegraph office with telephones to his ears, tracing the effect of the foreign currents. The sounds were sometimes most remarkable. Occasionally they heard a slight scream, not unlike a scream of pain from a child. At other times sounds were heard which had been likened to a cry of a young bird. One explanation given was that as the wires swing across the lines of force of the earth, there was an electromotive force set upon these wires, and when there was a long swing there might occasionally be a summation of all these vibrations that would produce a succession of currents resulting in these peculiar sounds. There was a very troublesome source of foreign currents on their wires, due to the introduction of the alternate current system of generating the electric light. That occurred in the case of the London Electric Supply Corporation, who had given the Post Office very evident cause of their presence down at Deptford, in fact, most of their wires to the South had been more or less disturbed, and so great was the disturbance at one time, that it was felt at Paris. There was another source of disturbance due to the working of the tramways. It was felt at Blackpool, for instance, in the

taking up and setting down of passengers. Most of these that he had referred to were foreign currents due to effects—very well known effects of induction, easily measured—carried to immense distances. The phenomena Mr. Bennett had brought before them were really electro-chemical, due more to the ordinary elementary principles associated with the ordinary construction of batteries, and although they might be interesting, he did not think they were very serious. He thought if they had the slightest influence on the speed or accuracy of the work of the telegraph it would not have taken them forty years to secure evidence of their existence.

Mr. HEAVISIDE, Newcastle, said that in his district they made use of the effects to which Mr. Bennett had referred in their insulators. They were constantly removing iron wire and placing copper wire on the poles. The iron wire left behind it oxide of iron, and when they placed copper wire in position they gradually got the effects mentioned by Mr. Bennett.

Mr. BENNETT stated in reply that the effects he had brought before the Conference were entirely wet weather effects. Those mentioned by Mr. Preece were mostly noticeable in dry weather. Although the voltaic action, and polarisation of the bolts had not hitherto been noticeable, he thought the effect was due to the use of iron wire exclusively. Recently copper was replacing iron all over the country, and the results noticed hitherto might be expected to increase considerably. Respecting the disturbance which might be expected from a more extensive introduction of electric tramways, a gentleman from Boston who was in Edinburgh recently, had told him that they did not hope to make any great use of the telephone system after nine o'clock at night, owing to the fact that the electric light in Boston came into operation after that hour. The telephone system was very much worse now than before the electric tramways were introduced into Boston. The fact was very serious indeed, and had given rise to endless litigation between the Telephone Company and the various tramway companies in the States. This was a matter they must endeavour to guard against in this country. It must be done in one of two ways, either by compelling the Tramway Company to use metallic circuits everywhere, or by the Telephone Company using them themselves. (Applause.)

The Conference then adjourned, and the members, after lunching, were conducted over the Exhibition, devoting their attention specially to the electrical sections.

#### DISCUSSION ON PROF. AYRTON'S PAPER.

Mr. PREECE, who occupied the chair when Prof. Ayrton's paper was read, called upon Prof. Perry to open the discussion.

Prof. PERRY said it was impossible for them to be prepared to discuss a paper on so short a notice, a paper which had taken years of work. It completely transformed their old notions. He was astonished at the large working efficiencies that had been obtained. It seemed to him a thing of enormous importance that those observations had been made by those who had absolutely no pecuniary interest in the matter. He had no doubt that makers were perfectly honest, and the results they gave were fair, but he liked to have an utterly independent set of observations. He admired the ingenuity which had been shown in the designing of the apparatus for keeping the current absolutely constant during charge or discharge, at the same time it might appear to him as a personal waste of energy. It seemed to him a terrible thing that such an enormous amount of thought should be devoted to work simply for the general good of the profession, and not at all for the general good of the authors of the paper; he was sure that they had exceedingly little to gain, compared with the enormous amount of work.

Mr. KAPP expressed himself pleased with the efficiencies of the cell, he would, however, suggest that the discussion should be continued at the next ordinary meeting of the Institution, when everybody would have read the paper, it would receive the discussion it deserved.

Lord BURY said he had employed secondary batteries to a very considerable extent and had put them to searching practical tests, the result of which was that they could be relied up to a greater extent than was generally believed. There were many improvements now being made in the practical development of these cells, one of which had been lately initiated by his friend Mr. Barber Starkey (See ELECTRICAL REVIEW, July 18th), by which the rough usage to which they were subjected in the course of tramway traction, could be very much counteracted.

Mr. FRASER gave an account of some experiments which he had carried out three years ago in regard to the variation of resistance in relation to current. He was favourably impressed with the method adopted by Mr. Barber Starkey, but he would wait until the end of the life of cells to see proof of their superiority. After remarks by M. Hospitalier and Mr. Swan,

Mr. PREECE considered, before he called upon Mr. Smith to reply on behalf of the authors, it would be only fair to them that he (the Chairman) should make any remarks he had to make. He was bound to confess that at the present day there was no subject of greater importance to the electrical engineer than that of the proper performance of secondary batteries. They were coming into use more and more every day, not only for the comfort of those who have their houses lighted by electricity, but for those who travel by railway trains. In every branch of electrical engineering secondary cells were being used. The speaker dwelt upon the fact that there was a great prejudice against the use of

secondary batteries, and it was based on the supposition that they were very inefficient. Though a few of them had long felt that the battery was not quite so efficient, the majority would feel that the authors of the paper had done a great work indeed throughout the profession, the unmistakeable figures before them showed that a secondary battery was not a very inefficient machine. Again, it had an important bearing on the question of distribution of electricity over large areas. The favourite system at the present was to distribute currents over wide areas by means of alternating currents and secondary generators, but there were those who believed in the future of secondary cells and who thought the day was not far distant when secondary batteries would knock out of the field the secondary generator. He, the speaker, was not one of those. He firmly believed in the secondary generator. One great drawback, however, in this system, had been their very low efficiency, and this was attributed to the inefficiency of the battery. He had very good reason to think that it was due not to the secondary cell itself, but to the methods which were adopted to charge and discharge the cells. In connection with this there was a fallacy which was very widespread, and it was, that because in charging a secondary battery they work up to an E.M.F. of 2.4 or 2.5 volts, and in discharging, you get down to about 2.1 volts, therefore there was a loss of efficiency of 25 per cent. in the battery; it was one of the most absurd fallacies ever perpetrated, and its fallacy was shown by the tables of the makers of secondary batteries; it is perfectly theoretically possible to get as much out of your battery as was put in, but practically it is not so. One of the most important features of the paper showed that necessarily there was a loss of energy in the cells owing to the action at the surface and diffusion of energy into the surrounding atmosphere. Practical men had arrived at very much the same conclusions as the authors of the paper. It had always been satisfactory for them to find that their conclusions had been borne out by accurate scientific investigations. They had long ago come to the conclusion that the E.M.F. of a cell should never be allowed to fall one point. He referred to the use of cells in his own house, which had been there for several years, and he had not had the slightest flicker of the light, which was entirely owing to the fact that the cells had been treated as secondary cells should always be treated, with great care and consideration. Cells which they had in the Post Office six years ago were still in existence. He (the speaker) had never yet succeeded in breaking or using up a single cell he ever had in his possession. The first cells he had were the Elwell-Parker type of Planté. They had tried all the types of E.P.S. which were in existence, in his own house. He liked them at home to experiment with, and if anyone would submit a battery cell, he would not hesitate to replace them and give them practical tests. Practice had introduced another test, one of great value indeed, and he would continue to call most earnest attention of those who wished the cell to prosper, always watch the performance of the electrolyte, never mind the E.M.F.; take care of the internal resistance, and to measure the density of the liquid by means of a hydrometer. In his room at the Post Office a book is kept recording the density and performance of every cell, and they could tell at once how a cell was behaving. Mr. Barber-Starkey had referred to the fact that he had introduced soda into his cells. He (the speaker) was very much struck, when visiting that gentleman, to see in what beautiful condition his plates had been brought to, and he was shown it was entirely due to the use of soda. Mr. Starkey applied it in a very rough-and-ready kind of way, he bundled some carbonate of soda into the cell and there remained sulphate of soda, which mixed with the cell. He (the speaker) was so well satisfied that there was so much in this that he organised a long series of experiments, lasting for nearly two years, to determine the proper proportion which should bear between the use of soda and sulphuric acid, and the conclusion arrived at was as follows, the solution was tried in the E.P.S. type, which is a cell taking 45 pints of electrolyte, made up of 39 pints of water, 5 pints of sulphuric acid of the highest specific gravity, and 1 pint of saturated solution of sulphate of soda, and the plates looked as bright and as beautiful as one could wish them to be. In conclusion, the speaker said the apparatus used by the authors reminded one of that brought two or three years ago before the notice of the Institution by Mr. Edmunds.

Mr. SMITH, on behalf of the authors, briefly replied, and the meeting adjourned.

#### NEW PATENTS—1890.

11788. "Improvements in electric arc lamps." S. P. PARMLY. Dated July 28. (Complete.)

11817. "Improvements in electric light fixtures." F. H. ALDRICH. Dated July 29. (Complete.)

11862. "Improvements in electrostatic measuring instruments." W. E. AYRTON and T. MATHER. Dated July 29.

11863. "Improvements in electric switches." W. W. STRODE and C. G. GILL. Dated July 29. (Complete.)

11883. "Improvements in the distribution of electricity, and in the apparatus employed therein." T. TOMLINSON. Dated July 29.

12009. "Improvements in electric indicators and in bells, applicable also to other purposes." J. S. ROSS. Dated July 31.

12094. "An electric fuse for firing guns." R. MORRIS. Dated August 1.

12119. "An appliance for holding the brushes of dynamo-electric machines while being repaired." H. HOLLINGDRAKE. Dated August 2.

12169. "Improvements in and relating to apparatus for measuring electrical energy." L. A. W. DESRUILLLES and R. F. O. CHAUVIN. Dated August 2.

## ABSTRACTS OF PUBLISHED SPECIFICATIONS, 1889.

4484. "Improvements in the regulation of electric currents." W. M. MORDEY. Dated March 14. 8d. Relates to the use of a small apparatus which the inventor calls a corrector, resembling a transformer in construction, and consisting of a suitably laminated iron core or sheath provided usually with two coils of wire. The corrector is wound with two windings, one of comparatively fine wire, which is connected as a shunt to the secondary terminals of the transformer, and thus is in parallel with the lamps. The other coil is of a thicker conductor, and has a smaller number of turns, and is connected in series with the lamps—that is to say, it is connected between one of the secondary terminals of the transformer and one of the secondary mains, the other secondary main being connected directly to the other secondary terminal of the transformer. The shunt winding may be connected across the secondary and the series winding combined, that is across the lamp terminals, instead of to the secondary terminals. The two circuits of the corrector are arranged to be traversed by currents in the same direction. The shunt or fine wire winding of the corrector, which is called the initial winding, is designed so that when connected to the transformer alone it receives such a current that the iron receives a certain initial magnetisation. In this condition the corrector opposes a certain impedance, opposing E.M.F., or choking action to any small current through its series winding, the effect, when a small number of lamps is switched on, being to reduce the potential difference available in the secondary circuit, to a value somewhat below that existing at the secondary terminals of the transformer. On the passage of a larger current in the secondary circuit, as when more lamps are switched on, the opposing E.M.F. or choking action of the corrector becomes reduced on account of the saturation of the iron, and a larger potential difference is made available in the secondary circuit. This effect is produced with only a trifling expenditure of energy, and the corrector is not to be taken as equivalent in this respect to a resistance. 2 claims.

6520. "Improvements in or relating to electrical motors for clocks and similar apparatus." W. P. THOMPSON. (A communication from abroad by Günther and Louis Hoppe, of Germany.) Dated April 16. 6d. Has for its object a motor in which the power of an ordinary or permanent magnet is utilised to actuate a vibrating arm in one direction in such a manner that on the end of its stroke an electric circuit shall be automatically closed, which energises an electro-magnet, the power of which is used to return said vibrating arm. The arm being thus vibrated, the clock or other mechanism is actuated by means of suitable connections. 2 claims.

7796. "Improvements in supporting electric conductors." W. A. S. BENSON. Dated May 9. 6d. The inventor binds together the insulated conductors forming part of an electric circuit or part thereof by a wire or wires wound spirally around them, which wire gives an ornamental appearance to the conductors, and lessens risk of the conductors becoming injured. In order to take any longitudinal strain, he lays wires parallel to the conductors and within the spiral binding wire. Upon the outside of the conductors he passes a tube, screw-threaded on the outside; this tube is slotted to receive the longitudinal supporting wires and the end of the protecting wire, which are passed through inside it and turned backwards in the slots, a cap or outer tube is then screwed on, whereby the longitudinal wires and protecting wire are firmly held. This cap or outer tube has attached to it a disc or bracket to be fixed to the wall, ceiling, or other place from which it is desired to suspend the conductors. 2 claims.

7883. "Improvements in electro-motors and apparatus used therewith for dental and other purposes." T. CUTTRISS. Dated May 11. 6d. Consist of an arrangement for instantly stopping the rotation of the burr, drill, stone, or other tool actuated by the motor, by making use of an electro-magnet for actuating a clutch arrangement attached to the motor, the current for working the electro-magnet being preferably obtained from the same source as used for driving the motor. 2 claims.

8030. "Improved automatic switch for charging electric accumulators and like purposes." M. E. UNGER. Dated May 14. 6d. A disc of insulating material is mounted on a shaft revolving in bearings. Around the disc are a set of metallic coatings, corresponding to the number of contact connections to be made. The coatings are insulated from one another step like on the disc, their number being one more than the number of the series. On the disc there are also places not coated with metal which correspond to the several segments of the contacts. The contact surfaces are

passed over and alternately rubbed by springs in communication with the source of electricity, and which conduct the current to the metallic coatings from which proceed short metal strips, and from these latter short wire connections to contact rollers fixed insulatedly on the same revolving shaft as the disc. The rollers rotate in quicksilver vessels, insulated from one another, and in which dip springs that are in connection with the corresponding poles of the series. The uncoated parts of the disc serve upon the sliding off therefrom of the springs to interrupt the current from the contact surface in connection with the last negative pole of the series, until upon the further turning of the disc a spring once more comes in contact with a contact surface in connection with the negative pole of the corresponding series, so that by this means short circuiting between the poles of the secondary batteries is prevented. 2 claims.

8692. "Improvements in multiple switch board systems for telephonic exchanges and wire bands to be used therein." J. E. KINGSBURY. (A communication from abroad by the Western Electric Company of Chicago.) Dated May 24. 8d. The object of this invention is to dispose the wires at the rear of the switch board in such a manner that they may be spread out to the rear without occupying an undue amount of vertical space, and at the same time to change the positions of the different wires relatively one to another as they pass from section to section, so that no two telephone wires may remain in close proximity to one another for any considerable distance. This is effected by making up or weaving together the wires into flat bands, preferably of a depth of a single wire only. 7 claims.

9119. "Improvements in electric bells and indicators." E. T. FIFORD. Dated June 1. 6d. Consists of a pendulum, suspended in front of the bell from a stud or bracket. A small soft iron armature is fixed on the pendulum rod opposite the pole of an electro-magnet attached to the bell frame. When a current is sent through the bell coils, it also passes through the coil of the aforesaid electro-magnet, and attracts the pendulum; as soon as the bell stops ringing the pendulum is released and swings, indicating that the bell has rung. 4 claims.

9133. "Improvements in the manufacture of carbons or electrodes for electric lamps." H. H. LAKE. (Communicated from abroad by Messrs. Lacombe & Co., of Paris.) Dated June 1. 6d. The inventor places between discs or other pieces or layers of carbon a layer of a material composed of a mixture of carbonaceous and silicious substances, or any suitable composition or material which, while not interfering with the proper working of the lamp, will by reason of the better conduction of the electrical current ensure the retention of the arc in a fixed position, and the consequent steadiness of the light. The pieces or layers of carbon, with the steady substance above mentioned between them, are preferably subjected to a high degree of compression so as to consolidate the mass, and increase the density and homogeneity thereof and the duration of the electrodes. 5 claims.

9162. "Improvements in the armatures of dynamo machines." C. E. L. BROWN. Dated June 3. 8d. Claims:—1. The construction of a drum wound armature, in which the wires between which the maximum difference of potential may exist are completely separated over the whole armature and throughout their length by an interposed continuous sheet of insulating material, one half the wires lying at one side of the said sheet, and the other half at the other side. 2. The improved method of winding and insulating the wires of drum armatures, substantially as described with reference respectively to and shown in the drawings.

9304. "Improvements in switches for electrical purposes." W. BARNICOAT. Dated June 4. 6d. The inventor arranges segmental opposite plates on the base of the instrument, which are secured thereto by a screw, the said screws also clamping the terminal wires to each plate. He mounts a tongued contact-maker or breaker always in connection with one plate on a spindle of irregular shape, adapted to fit a key possessed only by those in charge of the plant, so that careless, mischievous, or insane persons (such as in an asylum) cannot tamper therewith. He covers this spindle by a guard plate with a hole to insert the key, and to prevent possibility of shock, he insulates the key part of the spindle from the contact-breaker in any suitable manner. To ensure the contact-maker or breaker being always "on" or "off," he mounts on it a cam or eccentric (which may carry a small friction roller if desired); this bears against a plunger set up by a spiral spring carried in fittings on the base. 4 claims.

9284. "Improvements in metallic telephone circuits." H. L. BURBANK. Dated June 4. 8d. Consists in certain arrangements of the circuits with respect to the several appliances at the several stations, whereby when all the stations are at rest the several call bell helices and call bell generators are serially connected in circuit, so that each station may receive a call from, or send a call to, the central station or exchange calls with each other, and whereby the calling circuit of both is opened when either station is using the line for conversation. 3 claims.

10801. "Improvements in electric lamps." H. PIEPER fils. Dated July 4. 8d. Claims:—1. In an electric lamp, the combination of a carbon rod, an electric circuit, two or more electrodes in contact with one end surface of said rod, one or more of the said electrodes being movable with its, or their, contact point or points lengthwise to the rod and means for pressing the movable electrode or electrodes against the end surface of the same, substantially as described. 2. In an electric lamp, the combination of a carbon-rod, an electric circuit, and two or more electrodes in

contact with one end of the said rod, one or more of the said electrodes being tubular and inclined upward from their points of contact with the carbon, substantially as specified. 3. In an electric lamp, the combination of a carbon rod, an electric circuit, two or more electrodes in contact with one end of the said rod, one or more of the said electrodes being movable, means for pressing the movable electrode or electrodes against the carbon rod, contact surfaces on the movable electrode or electrodes, other contact surfaces arranged opposite thereto, and each of which is conductively connected to the pole of the lamp, being of different denomination from that to which the corresponding movable electrode is connected, substantially as set forth.

20260. "Improvements in electric semaphores for railways." F. STITZEL, C. WEINDEL, A. REUTLINGER, M. J. SCHWARTZ, J. H. EGELHOFF, and J. KREIGER, Sen. Dated December 17. 8d. The object of the invention is to provide an electric semaphore apparatus which shall be simple in construction and effective in operation. A further object is to provide an electric semaphore apparatus which shall be sensitive and positive in operation, and require but a small amount of battery to operate it. A further object is to construct the device that its signal blade may be made to stop at each half revolution, to impart different information according to its position—said blade being entirely hid within a shield when in a vertical or "safety" position. A further object is to construct an electric semaphore in such a manner that a visual blade and night signal may be operated by the same mechanism. A further object is to provide an electrical semaphore apparatus with a rotary signal blade and a night signal, both of these signals being operated simultaneously by the same mechanism. 11 claims.

## CORRESPONDENCE.

### The Lineff System of Electric Traction.

I trust you will allow me brief space for replying to Mr. Lineff's courteous answer (in your last week's issue) to my recent remarks upon his system; not desiring to be esteemed by anybody as one of that sadly too numerous class who rush into places—especially into print—where angelic beings even are remarkably afraid to venture.

Since writing, a fortnight ago, I have had the advantage of being "personally conducted" over Mr. Lineff's system, so as to see all the ins and outs thereof; and, in the first place, as a result, I want to say that his new method is certainly a very great advance on the old. In my humble opinion, indeed, it ought to prove fully the best, in point of first cost and working expenses, of all the underground systems hitherto devised.

But one still cannot help feeling that Mr. Lineff has a little further to go before reaching perfection; and though suggestions from an outsider are perhaps ill-timed, yet the necessity for a more solid foundation as regards the magnetic rail sections, constantly is prompted to the mind.

I certainly believe that a continuous channel of cement set in the asphalt insulation would prove more serviceable than the tiles which Mr. Lineff proposes to employ.

The incessant jarring of wheels upon the numerous exposed rail-edges (which must result from the different coefficients of wear or compression in iron and asphalt) ought very soon to show how much the earthenware tiles—which support the magnetic rail sections—can stand in the way of blows.

It would be very interesting to watch the effect which the ordinary street traffic will produce upon the inch thickness of asphalt underneath the tiles.

If the bottom of a very thick layer of asphalt remains fairly elastic whilst a hard skin is formed by traffic on the exposed top, then it might be found that the iron and asphalt surfaces would settle down at pretty much the same rate.

With regard to the question of surface leakage, it appears almost as though the report did not say enough for the line, for the test which resulted in the lowest figure for insulation was decidedly abnormal.

The difference between the highest and the lowest is so great that anyone might well be excused for thinking there was a "nigger" in it.

Thus measurements taken at various times might

show resistances of 4,000, 3,000, 3,500, 3,700, 3,200, 2,750, and so on, with, perhaps, one abnormal record of 600. In a case like this, one would say that the average re-

sistance is certainly not  $\frac{4,000 + 600}{2}$ , but considerably

higher. The fault lies in not taking a sufficient number of instances.

I still, however, think that a wise man will only reckon with certainty upon his lowest figure, even though it be somewhat abnormal. Twenty per cent. dividends from a company that is only supposed to pay five are pocketed with far more cheerfulness than 25 per cent. from one that ought to give 30.

Another point to be mentioned is the diminished size of motor required for the Lineff car as compared with accumulator cars. But Mr. Lineff knows quite well that the output of motors increases in much greater proportion than the lineal dimensions and mass, or weight, either; and a very little extra weight in the motor is enough to give the increased power required by reason of the accumulator dead-weight.

As for the weight of the car itself, the present car frames are amply strong enough to carry the accumulators, and nothing need be added for that purpose.

I am sorry the illustrations of this system, published before my last letter, escaped my notice. I usually devour most of the technical journals, more or less dyspeptically, but lack of time must have caused me to overlook this item. It makes no difference, however, as Mr. Kapp's report contained a very good verbal description of the line.

I am glad to hear that the Lineff system is shortly to be tried on a larger scale in practical work along the West Metropolitan Company's line (subject to the permission of that august body, the Hammersmith vestry), and I sincerely wish Mr. Lineff every possible success. Every electrical engineer is anxious enough to see electric traction introduced all over this country, and, personally, I do not wish in any way to act as a brake upon invention. I only hope to be convinced that the Lineff system will, for some time to come, be able to show publicly the great benefits of electric traction, so that later on the converted Englishman will calmly submit to overhead tramway conductors, or anything else that is reasonable.

Frank B. Lea.

### Fall of Potential.

I have an engineering pocket book which gives me the loss of potential in 100 yards of, say, a strand of 7/16s, with a current of 10 ampères, which is used at the distant end. The loss of potential is given as 2.21 volts on the basis of the 1,000 ampères per square inch section of conductor. Now, I understand how to arrive at the loss of potential, if I either increase or decrease the length of my cable, keeping the current constant; but, suppose I want to pass 15 ampères through a length of 75 yards, what is then the fall, length and current both being altered?

Works Manager.

[The fall of potential along any wire is simply the current passing multiplied by the resistance between the two ends of the wire. In the example you give you have taken the fall of potential over *half* the circuit only instead of over the whole length, viz., 200 yards. If the wire has a resistance of .11 ohm per 100 yards, then the resistance of the total circuit (200 yards) will be .22 ohm, and as the current is 10 ampères, the fall of potential will be  $.22 \times 10 = 2.2$  volts. For a total length of 75 yards, i.e., a loop of 37.5 yards, the resistance will be  $\frac{75 \times .11}{100} = .085$  ohm, and if the current be 15 ampères the fall of potential will be  $.085 \times 15 = 1.275$  volts. For a loop of 75 yards, i.e., a total length of 150 yards, the fall of potential from end to end would of course be double, i.e., 2.55 volts.—EDS. ELEC. REV.]

### M. GRAMME.

IN the report presented by the Comité des Arts Economiques to the Société d'Encouragement pour l'Industrie Nationale, in which M. Gramme's title to be awarded the Grande Medaille d'Ampère is set forth, M. Mascart reminds the committee that it is to Pixii, under Ampère's guidance, that we owe the first machine which has enabled us to dispense with chemical combinations in obtaining electrical currents. Thereafter the chief difficulty was to manipulate the natural alternation of these currents, so as to give them a like direction in the exterior circuit. Except in certain particular applications, arc lighting, for instance, where the inverse direction of the currents presented no inconvenience, the difficulty appeared to be insuperable. We can understand, therefore, the revolution that took place when, in 1869, M. Gramme invented his machine. It may be said that, for Paccinotti, the discovery existed in principle already, but, if so, this must have been unknown not merely to Gramme, but also to the scientific world, or how account for the astonishment which Gramme's discovery evoked? It must be borne in mind also that the feeling among competent persons was not altogether of a nature to encourage a comparatively unknown inventor, for it must be remembered that Gramme, who was then a simple workman, had but lately arrived in Paris, knowing merely how to read, write, and cipher, in addition to having some ideas of design picked up at odd moments. The best judges proved shortsighted in this case—even Breguet, who had received the inventor with his customary kindness, and defrayed the cost of patenting the invention, could hold out no hopes as to the future of the invention. Ten years later, at the International Exhibition of 1881, there was not a machine of old or new-world construction that had not its Gramme ring, and it is due to M. Gramme that Frenchmen are able to boast that the first alternating current machine and the first continuous

current machine were both constructed in France. It is these immense services rendered to the industry in general, and particularly in France, that the society desires to honour, and to this effect it has been decided to award to M. Gramme a special medal bearing the effigy of Ampère, thus at the same time rendering homage to the immortal creator of electro-dynamics.

### M. FERDINAND CARRÉ.

GENERAL SEBERT, in presenting the report of the Comité des Arts Economiques to the Société d'Encouragement pour l'Industrie Nationale, in which M. Ferdinand Carré's claims to the Henry Giffard prize of 6,000 francs for the most signal services rendered to French industry are set forth, observed that M. Carré's investigations in the artificial production of cold, and the manufacture of carbons for use in electric lighting, had had considerable influence on the industrial world. It was owing to M. Carré's investigations under the latter head that certain recent developments in electric lighting had been possible. The manufacture of carbons for electric lighting was at first by means of Foucault's method of pointing the carbons, a method capable only of producing an irregular and expensive article. That was in 1868. It was then that M. Carré, in a note addressed to the Academie des Sciences, pointed out a process by which some of the drawbacks of the Foucault process could be avoided. In 1876 he patented his draw-plate method, to which he subsequently added improvements with a view to securing regularity and excellence. These improvements included the composition of a carbonaceous paste and the choice of an adhesive liquid as well as ingenious processes for the burning, drying, and the impregnating of carbons under heat, by means of vacuum and compression; and it is due to them that the use of Jablochkoff candles has been possible. The sale of drawn carbons

has been considerable from the outset. With a view to modify the tint of the arc and to get rid of the incandescent particles projecting from the superficial strata, M. Carré first devised a hollow carbon furnished with a core of different composition, next a process whereby the carbons were impregnated with various salts subsequently removed from the outer layers by solution, so that only the core remained impregnated. These improvements he patented in 1878 and 1886. He also succeeded in producing a carbon to give out a red light. The fluted carbon, which is largely used in England, and was the subject of a patent in 1886, we also owe to M. Carré. Unfortunately, owing to these inventions not having been patented abroad, they are used without let or hindrance in foreign countries, and the inventor's profits are consequently greatly curtailed. But the services of M. Carré are freely acknowledged; and, in awarding the Giffard prize to him, the society is acting in accordance with the popular verdict.

### HOIST WITH HIS OWN PETARD.

"A GOOD letter has laid the foundation of many a man's prosperity." If there is any truth in this maxim, then, a correspondent, whom we assume to be very youthful, and whose communication upon cable-testing appears in another column, commences life with a good augury for his future career.

We need not refer to the *raison d'être* of Mr. Hall's letter, for it explains itself. The characteristics of such compilations as his should be conciseness and perspicuity, and on these points the gentleman, whose wrath we have incurred, is strong indeed; with the exception of a few terms of compliment, not a superfluous word should be admitted, and in this respect our correspondent is rigorously exact; indeed, the composition may be characterised as one of those efforts of polite letter-writing, in which all words not absolutely indispensable are omitted, giving rise to a forcible style, in which will be found all the essentials of true elegance.

While regretting that we do not number Mr. H. Cuthbert Hall amongst our regular readers, we can still congratulate our contemporary, whose devotion to submarine cable interests is supposed to be the sole object of its existence, upon having secured a contributor of such originality in research, and upon whose broad shoulders the mantle of Faraday is evidently destined to fall.

In reality, the matter at issue is so simple, old, and utterly unimportant, that we should not have entered into any discussion except out of sheer good nature to Mr. Hall, whose error in this respect, might, on some future occasion, lead him into one still greater if his vapourings were not checked with a firm hand and good intent withal. Why our correspondent should characterise the simple statement that his device is old, as unscientific criticism, is best known to himself. Moreover, that assertion is not argument, nor inaccurate

statement, proof, are truisms not unknown to us, but in how much our remarks justify Mr. Hall's reminder can best be seen by the appendices to his letter.

Probably after a perusal of these, Mr. Hall will regret having sent us a communication which can scarcely be said to comply with the precept,

"Adopt with every man the style and tone  
Most courteous, most congenial with his own."

unless, indeed, he is utterly devoid of sentiment of this nature.

It remains now to be seen whether, after our acceptance of the challenge thrown out by him, and the complete vindication of our statement that the method of cable testing he described is neither novel nor interesting, he will have the manliness to apologise for his hasty and ill-advised epistle.

### THE PETROLEUM ENGINE COMPANY, LIMITED.

THE company formed in 1888, for the development of the petroleum engine industry, by the manufacture of engines under the patents of Etéve, Hume and Priestman, for the United Kingdom and the British Colonies, including Canada and India, has just issued its annual report. It appears that the royalties received show a steady progression from £18 in 1888, to £559 and £1,035 in 1889 and 1890 respectively, and out of these amounts the directors' fees (£400) and other expenses of management, together £605 *per annum*, have to be deducted. At this rate, another three or four years will probably be passed before a modest 5 per cent. can be received by the shareholders, and it seems a convenient opportunity to now consider whether some changes cannot be made which shall tend to the return of the capital expended as the lives of the patents expire, and also to a reasonable interest on it during that period.

The utility of the engines has been amply demonstrated for many purposes, such as electric lighting, chaff cutting and threshing, driving lathes and tools, pumping, driving dairy and bread making machines, &c. In regard to the use in conjunction with dynamo machines, we have always had a high opinion of the engine's merits, and as the company possesses many first-class testimonials from practical and well known users, the difficulties incidental to the introduction of a new engine should by this time have disappeared.

The fees of the directors, £100 each, we think should be voluntarily reduced, seeing that the management is of an almost nominal character, Messrs. Priestman Bros. having not only the manufacture but the sale of the engines also, mainly in their hands.

It would be very interesting to know how much Messrs. Ernest Scott and Co., the second firm licenced, have done, what amount of royalties has accrued from their manufacture, and if but little (for we see no mention of their name in this year's report), why it is so. Have they had all facilities for making engines of the latest patterns, and if not, why not?

It seems likewise desirable that the petroleum engines should be well pushed in the colonies and India; are they being introduced there with all the energy and tact that can be brought to bear upon the business?

The directors have a really good thing to manage, and if those who now manufacture cannot go ahead faster, surely others can be found to undertake the work, so that the shareholders may soon have an opportunity of getting for their outlay at least some interest thereon.

#### Localising Faults in Insulated Wires.

AT Silvertown, the insulated trough method of localizing faults is no longer in use. It was found that when the core was covered with any fibrous material, the passing of it through a trough of water was too slow a process, as, unless the fault was a very decided one, it was necessary to proceed slowly, to allow the covering to get soaked. Mr. Hawkins has used a method which is as follows:—The core to be examined has one end sealed; beginning with this end it was wound on a drum which revolved in a trough of water, the latter being to earth. The other drum from which the core was being unwound had a hole through the side, through which the end of the core protruded, and was fastened by a screw to a brass or copper disc carried by an ebonite collar fitting on to the drum spindle. Contact was made by a spring which pressed against the periphery of the revolving disc, the other end of the spring having a lead to battery and galvanometer. Mr. Hawkins found that the drum upon which the cable was wound being in water, there was no fear of having the fibre insufficiently soaked. At Siemens's works the method devised by their electrician, Mr. F. Jacob, and described in Kempe's Handbook, has been in use some 15 years. The whole point of the method lies in having the external coating of every portion to earth, except that which is connected through the galvanometer to earth; thus the resistance along the outside of the wet core being considerably higher than the resistance of the galvanometer, any current through the fault in the portion connected to the galvanometer goes mostly through that instrument, whereas if the other portion is only on insulated drums, and the outside of the core is not perfectly insulated between that and the portion connected to the galvanometer, any small fault is most difficult to localise.

#### The P. M. G.'s Progress.

MR. RAIKES has caused questions to be asked by circular letter of those having registered telegraph addresses: 1st, as to whether the addressee has any objection to the publication of his registered address. 2nd, as to whether, if a list were published (of addresses in London), the addressee would wish to have a copy, the fee for registration, together with a quarterly copy of the list, being two guineas a-year. The idea of issuing a list seems to be a very good one, but to be thoroughly useful it should be extended to the whole of Great Britain—i.e., all telegraph addresses in the United Kingdom should be brought into one list. This list, we think, need only be issued annually, and in that case it might be found possible to bring it out for the extra guinea to be charged beyond the usual guinea for

the registration. For a list of London addresses only we consider a guinea by far too high a price. We do not know what number of registered addresses there may be in the whole of Great Britain, but this may be said safely that the greater the number the larger would be the demand for the list, and consequently the cheaper should be the relative cost of its production.

#### The Need for a Pacific Cable.

THE Melbourne *Evening Standard* of July 14th, 1890, has a somewhat lengthy article on the subject of the Pacific cable, and, having pointed out the various disadvantages of other routes, says:—"Against these many disadvantages the Pacific route offers a security in that throughout its entire length—across Canada from Vancouver to Hawaii, Fanning Island, Samoa and New Zealand—it would only touch foreign territory at Honolulu and Tutuila, while, as experience has abundantly proved, the greater depth at which the cable would lie would render it less liable to injury through volcanic disturbance, besides giving it greater protection against any hostile attempt at severance. In recognition of the advantages which the enterprise of the Eastern Extension Company has secured to Australia, Sir John Pender should be dealt with in a fair and liberal spirit. But it should not be forgotten that the benefit has been mutual, and that the Australian share would be terribly discounted if, by losing interest in the Pacific cable, it were to sacrifice its safety." We are glad to see the Melbourne Press fully alive to the true interests of the Colonies in the above matter, and sincerely trust that through such means the public opinion of Canada, Australia and New Zealand may be guided to the successful carrying out of this absolutely necessary enterprise.

#### Telegraph Poles for Advertising Purposes.

A MELBOURNE (Australia) paper says "there is every reason to believe that an arrangement will be entered into whereby the present unsightly wooden poles which support the street telegraph wires will be transformed into advertising hoardings, with due regard to the æsthetic cravings of the pedestrians. It is claimed that no damage will be done to the property of the Post Office, and that while the City Council will take proper precautions to prevent the impeding of traffic, the advertising company will substitute symphonies in gold, pink, and azure for the black tar besmirched posts, whose ugliness is but hardly excused even on utilitarian grounds." On reading the first few lines we were struck with horror to think what such a similar arrangement might do for our English towns, for although it is conceivable that harmonious designs by Burne Jones, Edward Poynter, Walter Crane, Whistler and others might prove interesting, nay, even instructive to art lovers among the public, yet we fear that in but too many cases colour and form would be sacrificed to giving prominence to the commercial aspects of the announcements. Telegraph poles, at any time, appear as defects in a landscape, but transformed into "advertisement hoardings" they would be simply atrocious, unbearable. Happily, however, there is not much fear that our Postal Department would be a party to such an arrangement as that indicated above, even though impertuned to be so.

FRANKLAND'S RESEARCHES ON THE  
CHEMISTRY OF STORAGE BATTERIES.

THE chemical changes which take place during the charging and discharging of storage batteries have been the subject of considerable difference of opinion amongst chemists and physicists. Some authorities have maintained that the effects are dependent on the occlusion of oxygen and hydrogen gases on the plates, whilst others, regarding the question from another point of view, have held that lead sulphate plays an important part in the phenomena. That the differences of opinion amongst experts have been widely divergent may be recognised from the fact that scientists, who, apparently, are well competent to express their views, have asserted that no chemical change of the lead sulphate occurs either in the charging or discharging of the plates.

In order to test the accuracy of the former opinion, Dr. Frankland, some time ago, undertook a series of experiments, the results of which were communicated to the Royal Society (*vide* Proceedings Royal Society, XXXV., p. 67). Two plates of lead were twisted into a corkscrew form, the gutter of the screw being filled with red lead; these plates were immersed in dilute sulphuric acid and charged in the usual way. When these plates were subsequently heated and the gas evolved, collected and examined, it was found that mere traces of oxygen and hydrogen were expelled, whereas, if the theory had been correct, there should have been a copious evolution. Hence, it was concluded, that the important agent in the cell is not constituted by the occluded gases.

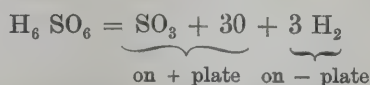

With regard to the lead sulphate, Dr. Frankland observed that in charging a strong cell, a considerable amount of sulphuric acid disappears, and is accompanied by a certain deposition of lead sulphate, but that the deposit formed is inadequate to account for the total acid which has disappeared.

The strength of the acid ceases to diminish and afterwards increases as the charging of the cell proceeds; this change continues until the maximum charge has been reached, and oxygen and hydrogen gases are evolved from the positive and negative plates respectively.

When the cell is discharged, the phenomena above described are reversed, the specific gravity of the acid decreasing from the point from which it began to increase on the charging of the cell.

From these experiments and the observations made upon them, Dr. Frankland deduced the following results, representing the changes which occur in charging a storage battery, viz.:

1. The electrolysis of hexabasic sulphuric acid (*i.e.*,  $H_6SO_6$ ) according to the equation

2. The reconversion of the evolved sulphuric anhydride ( $SO_3$ ) into the corresponding acid ( $H_2SO_4$ ).

3. Chemical action on the coating of the positive plate according to the equation

4. Chemical action on the coating of the negative plate according to the equation

When the storage battery is *discharged*, the first two changes observed in charging the battery are repeated. Further, on the coating of the positive, formerly the negative electrode, the chemical change which takes place is represented by the equation

on the coating of the negative. Finally, the positive electrode, the change occurring is represented by the equation

Hence Dr. Frankland formed the opinion that the formation of the cell consists in the more or less thorough decomposition of those portions of the lead sulphate comparatively removed from the conducting metallic nucleus of the lead. Lead sulphate possesses a low specific conducting power, whilst lead peroxide, and especially spongy lead, offer comparatively little resistance to the current, which is thus enabled to bring the outlying portions of the coating under its influence.

Since these results were published, Dr. Frankland has been pursuing his researches in the same direction. He undertook a series of experiments with a view to ascertaining what lead compounds actually take part in the chemical reaction in charging and then discharging secondary batteries.

A quantity of lead oxide ( $PbO_2$ ) reduced to a fine powder was treated successively with portions of dilute sulphuric acid until the liquid became permanently acid. On being allowed to stand, a buff-coloured precipitate separated from the mixture and was found by analysis to possess the formula  $Pb_5S_3O_{14}$ .

When finely powdered lead ( $Pb_3O_4$ ) was treated in the same way with dilute sulphuric acid, the powder which settled on standing was brownish-red in colour, and was found on analysis to have the constitution  $Pb_3S_2O_{10}$ .

Dr. Frankland considers that these hitherto unknown or undescribed salts constitute the original active material of storage cells, and that the following equations accurately represent the reactions which take place on the surface of the plates on charging and discharging the battery.

A. If the buff-coloured salt is the active material used, then

I. on charging—

II. on discharging—

B. If the brownish-red coloured salt is the active material used, then

I. on charging—

II. on discharging—

It is worthy of remark that in practice, only half as much material seems to be necessary for the negative as for the positive plates, and this is evidence in favour of the latter alternative, B, being correct.

We cannot assume, however, that there is nothing more to be discovered concerning the chemical action of storage batteries. The subject is full of complications, and it is to be hoped that electricians will receive further and large assistance from chemists who alone, perhaps, are able to throw the necessary light upon these obscure matters.

## EDINBURGH EXHIBITION.

(Continued from page 126.)

*The Barothermotelemeter.*—With Mr. Johnston Stephen, of Edinburgh, the Lord Justice Clerk is joint inventor of this instrument. It is for the purpose of enabling observers to take readings as often as desired, and by a single wire, from barometers and

thermometers placed at great heights or distances, without the necessity of the observer being resident where the instruments are placed, thereby saving much expense, and enabling observations to be taken at points where residence might be impossible. The barometer has inserted in its mercury a rod of insulating material, on which a screw thread has been cut, and on this thread a fine wire is wound. An electric circuit, established through this coiled wire to the mercury, and by a conductor from the mercury to earth, will, of course, meet with more or less resistance, according to the height of the barometer, as the coils are more or less short-circuited by the mercury. The thermometer has two carbon threads passed down into the mercury, and in the same way as in the case of the barometer the resistance is increased or reduced by the fall or rise of the mercury lengthening or shortening the circuit through the carbon threads. The procedure by the observer at a receiving station consists in taking, first, a reading of the line resistance, without passing the current through the instruments, then passing the current through the instruments in succession, and taking readings, correcting these by the reading of the line wire. The mode in which these changes are

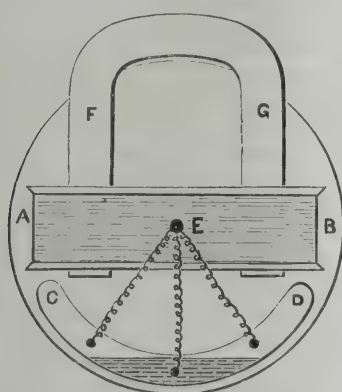

FIG. 1.

accomplished is shown in fig. 1. The flat coil, A, B, is balanced on the pivot, E, and the permanent fixed magnet, F, G, rests within the coil. On the circular disc, to which A, B is attached, a curved tube, C, D, is placed, which has a metal plate along its lower side, and a small quantity of mercury (shown by the shading).

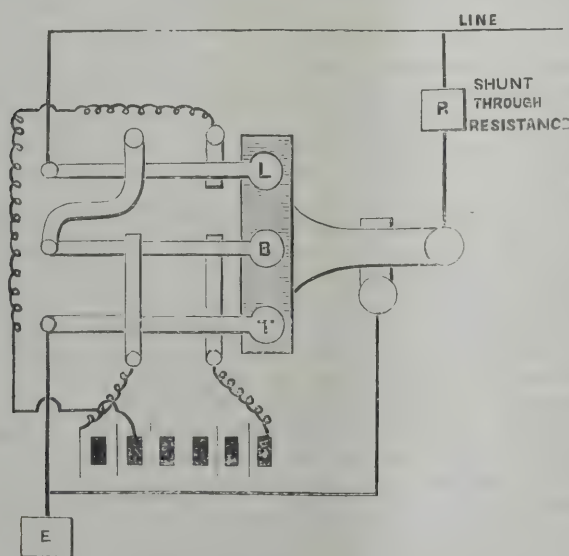

FIG. 2.

Three wires are inserted in the upper side of the tube—one in the centre, and one near each end. When the tube, C, D, is at rest a weak current passed from the line through the centre wire will not disturb the position of C, D. The line resistance can thus be noted.

If a strong + current be then passed, C, D is moved so that the mercury leaves the centre wire and makes contact with one of the side wires, and thus shunts the circuit from the line through the barometer circuit, the resistance of which is then checked. The thermometer is then checked by passing a strong - current, which turns C, D in the opposite direction, and makes the circuit through the other side wire. The mode in which these switchings are accomplished at the observing station is shown in fig. 2. It will be seen that when the key, L, is used a weak current passes to line, when the key, B, is used a strong + current passes, and when the key, T, is used a strong - current passes. In each case, when the key is still further depressed, it gives the current an alternative path through a bridge and proportional coils, thus enabling the readings of the resistance to be taken. The upper side of the large key, which connects the rheostat, is covered with insulating material to prevent short-circuiting.

### A NEW FORM OF GAS BATTERY.

AT one of the meetings of the Royal Society, a short time ago, a new form of gas battery was described by Messrs. Ludwig Mond & C. Langer. There are several forms of gas battery already known, but the peculiarity of this latest modification is that it is a *dry* gas battery.

The new battery may be thus briefly described:—A diaphragm of some porous non-conducting material, such, for example, as plaster of Paris, is saturated with dilute sulphuric acid, or with some other common and suitable electrolyte. This diaphragm is covered on both sides with thin platinum foil, which has been finely punctured, and which contains about 1,500 perforations per square centimetre. The foil is overlaid in its turn by a thin film of platinum black.

The internal resistance is reduced to a minimum by placing the foil in contact at short intervals with strips of some good conductor.

A number of such diaphragms having been prepared in the manner described, they are placed side by side, or one above the other, with non-conducting frames intervening; this arrangement forms chambers through which the gases employed are passed. One side of each diaphragm is exposed to the action of air or hydrogen, whilst the alternate sides are exposed to the action of hydrogen gas, and the spaces which exist between the diaphragm are so connected that the gases pass through the whole series each in its own proper way.

Experiments were made in order to estimate the electromotive force of such a battery as this, with the result that it (the E.M.F.) was found to vary considerably with the quality of the platinum black.

The best result obtained was:

$$\text{E.M.F.} = 0.97 \text{ volt,}$$

and this was yielded when platinum black, prepared as follows, was employed, namely, by precipitation from a boiling solution of platinum tetrachloride by neutralising with sodium carbonate, and afterwards reducing with a boiling solution of sodium formate.

The resistance of a plate of plaster of Paris, 8 mm. in thickness and having 350 sq. cm. of surface, was found to be

$$R = 0.02 \text{ ohm.}$$

The maximum amount of work was obtained from this battery when the external resistance was nearly double the value of the internal resistance.

After much experiment it was found most convenient to work the battery with an electromotive force of about 0.73 volt, which allows a current of from 2.0 to 2.5 amperes to be taken out of an element with 700 sq. cm. of active surface covered with 0.35 gramme of platinum foil and 1 gramme of platinum black. The temperature should be maintained constant at 40° C. by passing excess of air through the battery.

About one-half of the energy of combustion of the

hydrogen gas is converted into electrical energy; this is, comparatively speaking, a high value.

Messrs. Mond and Langer, besides experimenting with oxygen and hydrogen, also tried air and a gas containing from 30 to 40 per cent. of hydrogen—a gas, in fact, such as can be got by the action of steam, with or without air, on coal or coke.

As might be predicted, this battery after having been at work for some time begins to exhibit signs of polarisation. In the opinion of Messrs. Mond and Langer, this phenomenon is caused by a charge in the concentration of the acid at the two electrodes, and may be remedied by interchanging the gases from time to time; this can be effected with the greatest ease since the materials to be interchanged are gaseous.

It is only fair to remark, in conclusion, that Messrs. C. R. A. Wright and C. Thompson have recently stated that the gas battery described by Messrs. Mond and Langer is practically identical in principle with one described by them in 1888 in a paper entitled "On the Development of Voltaic Electricity by Atmospheric Oxidation" (*vide Proceedings Royal Society*, Vol. XLIV., p. 182), and which was perhaps foreshadowed in a previous paper by them, entitled "Note on the Development of Voltaic Electricity by Atmospheric Oxidation" (*vide Proceedings Royal Society*, Vol. XLII., p. 212.)

## A SYNTHETIC STUDY OF DYNAMO MACHINES.

(Continued from page 40.)

### IX.—THE HEATING OF MACHINES.

IN every dynamo there is performed internally while running a certain amount of work, first, in forcing the current through conductors having some resistance; secondly, in continually changing the direction of the magnetism in the armature core; thirdly, in generating in the latter feeble parasitic currents. The energy thus dissipated appears in the form of heat; accordingly the machine increases in temperature from the time it is started, and attaining a maximum when the rate of losing heat into the surrounding air is exactly equal to the rate at which it is generated in the machine. There is also, in addition to the above, some work done in overcoming the friction of the journals. As this need be no greater than in other machinery through which at the same speed similar power is transmitted, the heating arising therefrom calls for no special attention.

In fixing the heating limits, two things must be borne in mind. First, the temperature must not be great enough to cause deterioration of the insulating material; secondly, the variation must not be great enough to give trouble from the expansion and contraction of the metal parts. As regards the armature, there is some difficulty in measuring the actual temperature of the conductors. As a rule, they are covered all round with insulating material, and the usual way being to lay the thermometer on the insulation when the machine stops running, what is actually observed is, of course, the temperature attained by the outside covering. On the other hand, what we actually take the indication from is of little importance, provided the observation affords a guide as to whether the temperature of any part gets too great. It is certain that the wires next the core, in an armature wound with, say, four layers of .048 inch diameter wire, would be a good deal hotter than would be indicated immediately by a thermometer placed on the covering of the outer wires when the machine stops. At the same time if we know from experience, that the heating of the inside wires is harmless when the temperature of the outside covering does not with the thermometer left on exceed a certain amount, an observation of the outside temperature should furnish us with a perfectly

reliable guide as to what cooling surface should be allowed. In practice we can only measure the surface temperature, and, given a certain rate of generating heat, the temperature which the surface attains in running depends upon its extent and character, and on the speed of rotation. But the difference of temperature between the interior and the outside depends upon the thermal resistance encountered by the heat in flowing to the surface. In an armature wound with one layer of coarse wire, for example, it would require less difference of temperature to produce a given flow of heat than in one wound with several layers of fine wire. In the former there is only one layer of cotton insulation for the heat generated in the copper to flow through, while in the latter the flow to the surface takes place partly by conduction round and round the fine wire and partly through the several layers of badly conducting cotton covering. But by leaving the thermometer on the machine, and noting the maximum to which it rises, we can readily obtain an idea of the temperature to which the underneath insulation is subjected.

The interior of the core is always hotter than the underneath layers of wire, even if the heat generated in the iron itself is small. When the armature is built of plates the difference in temperature between the interior and exterior of the core is little, as the iron forms a continuous conductor which carries off the heat fairly well; but if constructed of iron wire the difference is greater, as the flow of heat is obstructed by badly-conducting substances (cotton covering, varnish, &c.). When a machine is started the heat flows from the copper into the surrounding air also into the iron core, the latter being for a time the cooler. As the run continues the core increases in temperature from this reception of heat, also on account of a certain amount being generated in its own mass. Its temperature becomes in time equal to that of the adjacent conductor, when it neither receives nor loses heat. Finally, it rises above that of the conductor by an amount just sufficient to cause its heat to flow outwards through intervening substances.

It will be seen, then, that the maximum temperature may not be attained for a considerable time, as, due to the absorption of heat by the core, the cooling surface is virtually large to start with, but gets less and less as the core attains its maximum. When the ultimate temperature is reached, the heat is radiated from the exterior surface only, and the heat thus radiated is exactly equal to the heat generated. The time it takes for the machine to reach its ultimate temperature varies considerably, as might be expected. Very often the maximum temperature is not attained in large machines until they have run for six or eight hours, while in smaller machines a two to three hours' run may be sufficient. For a thorough test, the machine should be run with full load until its temperature ceases to rise.

Some difference of opinion exists with reference to the temperature which should be permitted. The British Admiralty allow a rise of about 40° C. above the surrounding atmosphere, and engineers are generally specifying this limit for the contracts of which they have charge. The measurement is taken by placing the thermometer on the armature after the machine has stopped, and noting the maximum attained. It thus indicates something less than the actual temperature of the core and conductors, but affords a reliable enough indication as to whether the heating in these is too great. If the rise measured in this way does not exceed 40° C., the insulating material is considered to be in no danger of deterioration.

Remembering that the Admiralty dynamos have often to work in an atmosphere of some 50° C., this rise seems somewhat ample, while for land dynamos, working under ordinary conditions, it does very well. Mr. Esson, in his recent paper, stated as his opinion that in no case should the maximum temperature exceed 75° C. i.e., the temperature of the room added to the rise in continuous running. In the continuous running of an

Edison-Hopkinson dynamo for three weeks at full load the temperature of the armature varied from 76° C. to 84° C., keeping throughout the run about 60° above the surrounding air. In America they work much hotter, and accordingly we find the United Edison Manufacturing Company specifying that after a 10 hours' run at full load no conductor or other electric part of their dynamos shall have a temperature of more than 80° C. above the surrounding atmosphere. This, to British electricians, seems excessive, though the reflection that the American limit is not exceeded may, at times, comfort them, when, for some unforeseen reason, a machine runs hotter than usual. Speaking generally, a temperature limit of 75° C., which includes a rise of from 30° to 40° C., is not exceeded by the best English practice.

(To be continued.)

### TESLA'S NEW ALTERNATING MOTORS.\*

FOR some time past Mr. Nikola Tesla, whose previous work in alternating current motors is well known, has been engaged upon the study of these machines, in order to develop efficient methods for operating them on two wires instead of three, and still without the use of a commutator.

The general principle upon which these machines are designed is based on the well-known fact that if a magnetic core, even if laminated, be wound with a coil, and a current be sent through, the magnetisation of the entire core does not immediately ensue, the magnetising effect not being exhibited in all parts simultaneously. This Mr. Tesla attributes to the fact that the action of the current is to energise first those laminæ or parts of the core nearest the surface and adjacent to the exciting coil, and from thence the action progresses towards the interior. A certain interval of time, therefore, elapses between the manifestation of magnetism in the external and the internal sections or layers of the core.

If the core be thin or of small mass, this effect may be inappreciable, but in the case of a thick core, or even of a comparatively thin one, if the number of alternation be very great, the time interval occurring between the manifestations of magnetism in the interior of the core and in those parts adjacent to the coil is more marked, and in the construction of such apparatus as motors which are designed to be run by alternating currents, Mr. Tesla has found it desirable, and even necessary, to give due consideration to this phenomenon and to make special provisions in order to obviate its consequences.

On the other hand, by taking advantage of this very action or effect, and, by rendering it more pronounced, Mr. Tesla utilises it in the operation of motors in general. This he effects by constructing a field in which the parts of the core that exhibit at different intervals of time the magnetic effect imparted to them by alternating currents in an energising coil are so placed with relation to a rotating armature as to exert thereon their attractive effect successively in the order of their magnetisation. By this means there is secured a result similar to that which Mr. Tesla has heretofore attained in the previous types of his motor, in which, by means of one or more alternating currents, he produces a rotation or progression of the magnetic poles or points of maximum attraction of the field of force.

The general principle involved in the action above mentioned is illustrated in the simple motor shown in fig. 1. Here X represents a large iron core composed of a number of sheets or laminæ of soft iron or steel. Surrounding this core is a coil, Y, which is connected with a source, E, of rapidly varying currents.

Let us consider now the magnetic conditions existing in this core at any point, as *b*, at or near the centre, and any other point, as *a*, nearer the surface. According to Mr. Tesla, when a current impulse is started in the magnetising coil, Y, the section, at *a*, being close to the coil, is immediately energised, while the section, at *b*,

which, to use a convenient expression, is "protected" by the intervening sections or layers between *a* and *b*, does not at once exhibit its magnetism. However, as the magnetisation of *a* increases, *b* becomes also affected, reaching finally its maximum strength some time later than *a*. Upon the weakening of the current the magnetisation of *a* first diminishes, while *b* still exhibits its maximum strength, but the continued weakening of *a* is attended by a subsequent weakening of *b*. Assuming the current to be an alternating one, *a* will now be reversed, while *b* still continues of the polarity first imparted. This action continues, the magnetic condition of *b* following that of *a* in the manner above described.

If an armature, for instance, a simple disc mounted to rotate freely on an axis, be brought into proximity to the core, a movement of rotation will be imparted to the disc, the direction depending upon its position relatively to the core, the tendency being to turn the position of the disc nearest to the core from *a* to *b*, as indicated in fig. 1.

This action or principle of operation has been embodied in a practicable form of motor, which is illustrated in fig. 2. Here A represents a circular frame of iron, from diametrically opposite points of the interior of which the cores project.

Each core is composed of three main parts, B, B, and C, and they are similarly made with a straight portion, *e*, around which the energising coil is wound, a curved arm or extension, *c*, and an inwardly projecting pole, *d*.

Each core is made of two parts, B, B, with their polar extensions reaching in one direction and a part, C, between the other two and with its polar extension reaching in the opposite direction. These cores are wound with coils, D, which are connected in the same circuit either in parallel or series and supplied with an alternating current by a generator, E, represented diagrammatically. Between the cores or their polar extensions is mounted an armature, F, wound with magnetising coils, G, that are closed upon themselves, similar to those in the older types of Mr. Tesla's motors.

The operation of the motor is as follows:—When a current impulse or alternation is sent through the coils, D, the sections, B, B, of the cores being on the surface, and in close proximity to the coils, are immediately energised. The sections, C, on the other hand, are protected from the magnetising influence of the coil by the interposed layers of iron, B, B.

As the magnetism of B, B increases, however, the sections, C, are also energised, but they do not attain their maximum strength until a certain time subsequent to the exhibition by the sections, B, B, of their maximum.

Upon the weakening of the current, the magnetic strength of B, B first diminishes while the sections, C, have still their maximum strength; but as B, B continue to weaken, the interior sections are similarly weakened.

B, B may then begin to exhibit an opposite polarity, which is followed later by a similar change on C, and this action continues.

B, B and C may, therefore, be considered as separate field magnets, being extended so as to act on the armature in the most efficient positions, and the effect is similar to that in Mr. Tesla's other forms of motor, viz., a rotation or progression of the maximum points of the field of force. Any armature, such, for instance, as a disc mounted in this field, would rotate from the pole first, to exhibit its magnetism to that which exhibits it later.

In following out the ideas stated above, Mr. Tesla has applied them to a class of motors in which two or more sets of energising magnets are employed, and in which by artificial means a certain interval of time is made to elapse between the respective maximum or minimum periods of their magnetic attraction or effect. This has already been applied to the operation of Mr. Tesla's three-wire motors. In the present instance Mr. Tesla employs a motor with two sets of energising or field

\* *Electrical Engineer.*

magnets, each wound with coils connected with a source of alternating currents, but forming two separate paths or circuits. The magnets of one set are protected to a certain extent from the energising action of the current by means of a magnetic shield or screen of laminated iron interposed between the magnet and its energising coil.

The shield is properly adapted to the conditions of particular cases so as to shield or protect the main core

The engraving, fig. 4, shows the simplest form of this type of machine. The cores, B, form one set of magnets, and are energised by coils, D, while the cores, C, forming the other set, are energised by coils, E, and the coils are connected in series with one another, in two derived or branched circuits, F, G, respectively.

Each coil, E, it will be noted, is surrounded by a magnetic shield, H, which is composed of an annealed insulated or oxidised iron wire wound on the coils in

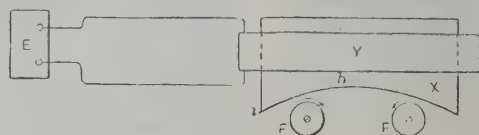

FIG. 1.—TESLA ALTERNATING MOTOR.

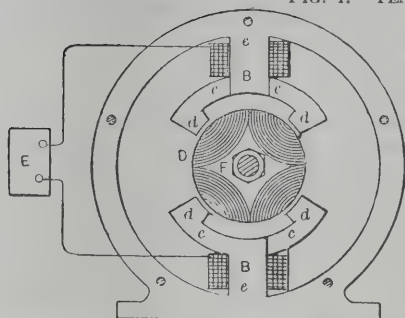

FIG. 2.—TESLA ALTERNATING MOTOR.

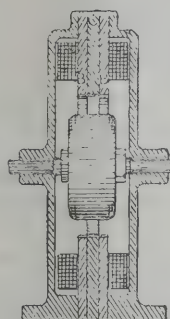

FIG. 3.—TESLA ALTERNATING MOTOR.

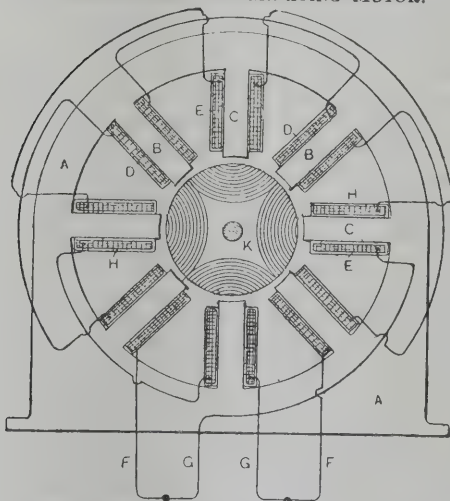

FIG. 4.—TESLA ALTERNATING MOTOR.

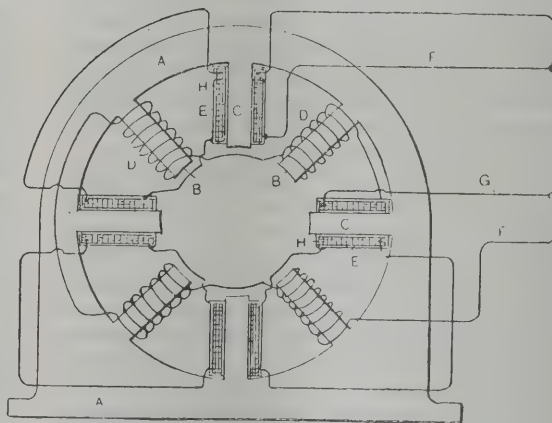

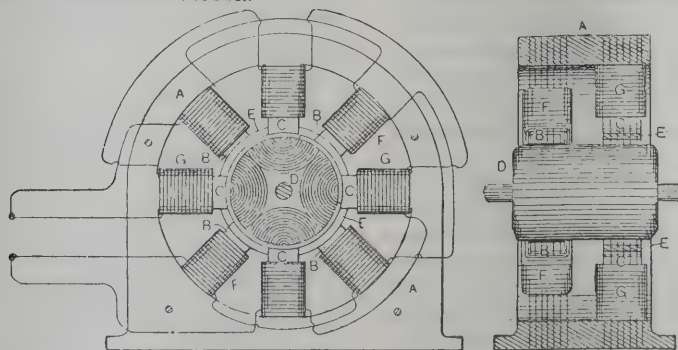

FIG. 5.—TESLA ALTERNATING MOTOR.

FIGS. 6 AND 7.—TESLA ALTERNATING MOTOR.

from magnetisation until it has become itself saturated, and no longer capable of containing all the lines of force produced by the current. By this means it will be seen that the energising action begins in the protected set of magnets, a certain arbitrarily determined period of time later than in the other, and that by this means a practically economical difference of magnetic phase may readily be secured.

The nature and operation of this motor will be readily understood by reference to the accompanying illustration.

the manner indicated, so as to form a closed magnetic circuit around the coils, and between the same and the magnetic cores, C. Between the pole pieces or cores, B, C, is mounted the armature of the closed circuit coil type.

The operation resulting from this arrangement is as follows:—If a current impulse be directed through the two circuits of the motor, it will quickly energise the cores, B, but not so the cores, C, for the reason that in passing through the coils, E, there is encountered the influence of the closed magnetic circuits formed by the

shields, H. The first effect is to effectively retard the current impulse in circuit, G, while at the same time the proportion of current which passes does not magnetise the cores, C, which are shielded or screened by the shields, H.

As the increasing electromotive force then urges more current through the coils, E, the iron wire, H, becomes magnetically saturated and incapable of carrying all the lines of force, and hence ceases to protect the cores, C, which become magnetised, developing their maximum effect after an interval of time subsequent to the similar manifestation of strength in the other set of magnets, the extent of which may be arbitrarily determined by the thickness of the shield, H, and other well-known conditions.

From the above it will be seen that the apparatus or device acts in two ways. First, by retarding the current, and second by retarding the magnetisation of one set of cores, from which its effectiveness will readily be seen.

Many modifications of the principle here embodied have been made by Mr. Tesla, one only more of which we may notice here. This is illustrated in fig. 5, and is similar in all respects to that above described, except that the iron wire, H, which is wrapped around the coils, E, is in this case connected in series with the coils, D. The iron wire coils are connected and wound so as to have little or no self-induction, and, being added to the resistance of the circuit, F, the action of the current in that circuit will be accelerated, while in the other circuit, G, it will be retarded.

Still another type of motor constructed by Mr. Tesla is one with a field magnet having two sets of poles or inwardly projecting cores, and placed side by side so as practically to form two fields of force, and alternately arranged, that is to say, with the poles of one set or field opposite the spaces between the other. The free ends of one set of poles are then connected by means of laminated iron bands or bridge pieces of considerably smaller cross-section than the cores themselves, so that the cores all form parts of complete magnetic circuits.

When the coils on each set of magnets are connected in multiple circuits from an alternating machine electromotive forces are set up in each circuit simultaneously, but the coils on the magnetically bridged or shunted cores will have, by reason of the closed magnetic circuits, a high self-induction which retards the current, permitting at the beginning of each impulse but little current to pass. On the other hand, no such opposition being encountered in the other set of coils, the current passes freely through them, magnetising the poles on which they are wound.

As soon, however, as the laminated bridges become saturated and incapable of carrying all the lines of force, which the rising electromotive force, and consequently increased current, produce, free poles are developed at the ends of the cores, which, acting in conjunction with the others, produce rotation of the armature.

The construction by which this is accomplished is shown in the accompanying engravings, figs. 6 and 7.

The frame of the motor, A, is built up of sheets of iron, punched out to the desired shape and bolted together with insulation between the sheets. When complete, the frame makes a field magnet with inwardly projecting pole-pieces, B and C. To adapt them to the requirements of this particular case, these pole-pieces are out of line with one another, those marked, B, surrounding one end of the armature, and the others, C, the opposite end, and they are arranged alternately; that is to say, the pole pieces of one are set in line with the spaces between those of the other sets.

The pole-pieces, C, are connected or shunted by bridge pieces, E.

The coils, F and G, are connected in series, respectively, in two circuits, which are branches of a circuit from an alternating machine, and they are so wound that the circuit of coils, G, will have a higher self-induction than the other circuit or branch.

The function of the shunts or bridges, E, is that they shall form with the cores, C, a closed magnetic circuit

for a current up to a predetermined strength, so that when saturated by such current, and unable to carry more lines of force than such a current produces, they will, to no further appreciable extent, interfere with the development by a stronger current of free magnetic poles at the ends of the cores, C.

In such a motor, the current is so retarded in the coils, G, and the manifestation of the free magnetism in the poles, C, is delayed beyond the periods of maximum magnetic effect in poles, B. The result is that a strong torque is produced, and the motor operates with approximately the power developed in a motor of this kind, energised by independently generated currents, differing by a full quarter phase.

## THE BREMEN ELECTRIC TRAMWAY.

As already announced in the REVIEW of the 11th ult., the first electric tramway in Europe on the Thomson-Houston system was opened in Bremen on the 22nd June. The length of the line, which forms a double track, except in one narrow street, is 1,748 yards, or nearly a mile. It commences at the Town Hall in the centre of the town and passing by the new railway station, terminates at Exhibition-place just inside the town park, where an industrial exhibition is now being held. The conductors, which are carried overhead, consist of copper wires 8.25 mm. in thickness, and are suspended from insulators attached to steel cables arranged transversely across the streets on steel and cast iron posts. The engine-house is situated about 220 yards from the starting point of the tramway and to the left side of the park entrance. It contains at present a Pétry-Déreux boiler, and a steam engine of 150 I.H.P., made by Küchen of Dusseldorf. This drives a dynamo having an output of 62,500 watts, at an E.M.F. of 500 volts at the terminals. There is also installed a 70 H.P. high speed Armington-Sims engine, and an arc light dynamo. Another dynamo, similar to the first, will shortly be erected. Current from this generating station is used for several purposes: for the working of the tramway; for operating a 15 H.P. electromotor placed in the Vienna Bakery in Exhibition-place, where the motor actuates several kneading machines, and a dynamo which supplies current to a number of arc and incandescent lamps; and for the lighting of many arc and glow lamps arranged on the tramway route, &c.

The current from the first dynamo goes from the positive brush to the main conductor, which is arranged at a height of 20 feet over the middle of the track and passes along it until it reaches a contact roller carried by the car. The current is collected by contact rollers, from which it passes to the two motors, then through the car wheels to the rails and thence back to the negative brush. It branches its course along the main conductor and is collected by the contact rollers on other cars in the same manner. The single rails are connected by copper wires rivetted to them. On the top of each car is erected, at an angle of 40 degrees, an iron supporting rod which carries a grooved contact roller pressing against the underside of the conductor. Suitable leading devices are arranged at crossings so that the contact rollers keep in position. There are two 10 H.P. motors to each car and they are fixed in a specially built framework. Each motor drives one of the two axles, and each car is fitted with brakes, track brushes for removing obstacles off the rails, and safety appliances. Throughout the line there are numerous curves most of which are of small radius, but these are all traversed with great facility. At present there are in service five to six passenger cars, to each of which a separate car can be attached according to the requirements of the traffic. A car dépôt has been erected in the rear of the gas works and several pits have been dug in order to render the motors readily accessible.

—Abstracted from the *Elektrotechnische Zeitschrift*.

## FIELD'S MAKE AND BREAK TELEPHONE.

MR. STEPHEN W. FIELD'S work in the various branches of telegraphy and electric railroading is probably well known to our readers, but his versatile genius has also led him in the direction of telephony. One of the results of his work here has been the production of a telephone which automatically makes and breaks its circuit with a rapidity too great to be perceptible to the ear; he combines this with a diaphragm in such a way that sound waves projected against it are caused to bridge over the makes and breaks to a degree exactly proportional to the sound waves' rapidity of succession.

The accompanying engraving, fig. 1, shows two such diaphragms, D and M, supporting respectively two contact points, E and G. One diaphragm is supported above the other, and is kept in a state of tension by connection with a fine wire, C, of considerable resistance.

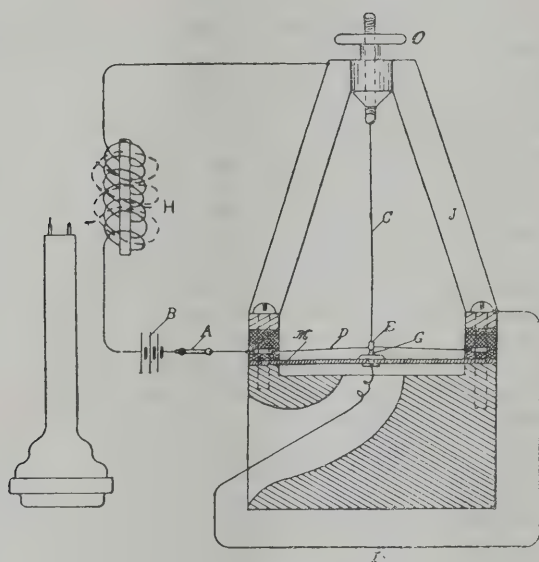

FIG. 1.

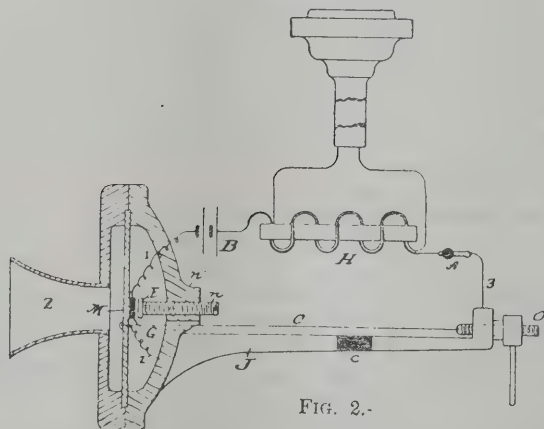

FIG. 2.-

It will be seen that the circuit of battery, B, passes normally through the insulated metal frame, J, of the telephone, and the wire, C, to the diaphragm, D. It will also be observed that there is a short circuit, by way of the wire, I, between the contact point, G, and the frame, J. The strain of the wire, C, is normally sufficient to separate the contact points, E and G, but when the switch, A, is closed and the current from battery, B, traverses wire, C, the latter will elongate and allow the points to come in contact. The current will thus be shunted around wire, C, through a path of approximately no resistance, with the result of cooling and contracting C and separating the contact points.

The function of the device is, in fact, that of a circuit-breaker of such rapid action under the influence of the current of the battery, B, that the vibrations are outside the receptivity of the ear. It follows that the sound waves striking the diaphragm, F, will alter the relative positions of E and G, and tend to prolong their contacts,

making audible, and, if in proper sequence, articulate speech.

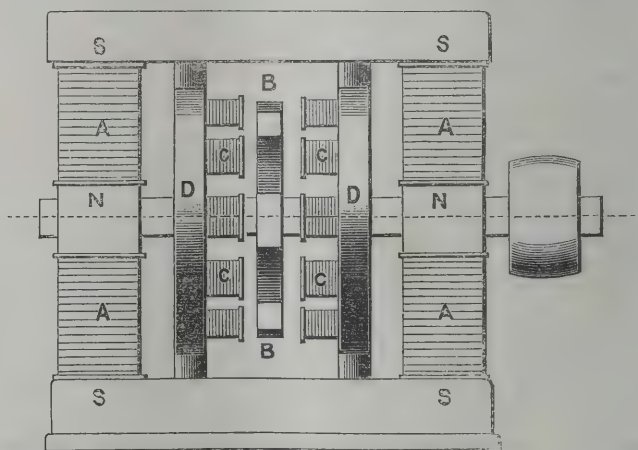

In fig. 2 is shown an arrangement for applying the same idea to a carbon transmitter for the purpose of increasing its sensitiveness. In this construction the carbon, which is mounted on the diaphragm, is kept in contact with a corresponding platinum contact piece by means of a fine wire under tension attached to the diaphragm. The contact expands the wire C, thereby tending to break the circuit; but the consequent cooling of the wire contracts the same and closes the circuit.

With the construction here illustrated an equilibrium is set up between the elongation of the wire, C, and the resistance at the carbon contact, the result being that the pressure of the carbon is kept automatically at the most delicate point and a self-adjusting carbon transmitter is obtained. The changed thermostatic condition of the primary circuit is brought about in this construction by a rupture of the circuit, due to the elongation of the resistance wire, or, rather, by an increase in the resistance of the circuit, and not, as in the other form, by the introduction of a shunt around the resistance wire.

The makes and breaks of the automatic circuit breaker produce no audible effects upon the circuit by reason of the great rapidity with which they follow each other. That is to say, the normal vibrations of the circuit breaker, considered with respect to their capacity to reproduce sounds, are neutral or inharmonious. That which reduces them to harmony and enables them to reproduce sounds is the combination, with the apparatus which produces them, of devices which bridge over or throw together more or fewer of the inharmonious vibrations and thus alter their natural sequence.

## AN HISTORICAL ALTERNATOR.

BY the courtesy of Messrs. Paterson and Cooper, we are enabled to give here a sketch of the Lever Alternating Current Dynamo, to which reference was made last week in our leading columns. On the two upright magnets, which also serve to carry the bearings for the star wheel, B, are four magnetising coils, A. The spokes of the wheel are eight in number, and there are 32 fixed coils, C (a few of which are shown), 16 being

arranged on each side of the wheel. The coil cores are fastened into the ring cheeks, D, D, while the whole is bound rigidly together by the sole and top plates, S, S. All the wheel spokes are of similar polarity, as the current circulates in the magnetising coils to produce poles, N and S, as marked. The sketch really explains itself, and the faults of the design will be as obvious as the resemblances to Prof. Elihu Thomson's machine described last week. The substitution in the latter of one circle of radiating coils for the two circles in Lever's is a distinct improvement, as is also the winding of the magnetising coils concentric with the axis, and employing two instead of four. The necessity for laminating the magnet wheel is one of the things that

Lever would have found necessary had he gone on with his machine. That he did not follow his ideas a little farther is a circumstance to be regretted, as it is highly probable that the process of evolution to which all new designs are subject would have produced a machine nearly similar in detail as it was in principle to the latest American novelty.

### THE MUNICIPAL ELECTRICAL WORKS AT TRIENT.

[FROM A CORRESPONDENT.]

THE following particulars are given on good authority concerning the electric illumination of Trient and the cost of the installation. The works are driven by water-power, and were erected by Siemens and Halske. The municipality of Trient has already paid upwards of 500,000 florins for the arrangement of the present water-power of the Fersina, amounting to 600 H.P., and in order to make sure of this power during the time when the river is low, they will have to tap the lakes on the Pine, which lie at the distance of 12 kilometers up the valley, so as to utilise them for making up the water supply if deficient, which with all the additional rights to be acquired, will involve a fourth outlay of at least 150,000 florins. The town, with a population of 20,000, expends, therefore, more than 650,000 florins for its electrical works, to supply 6,000 glow lamps or their equivalent in arc lights or in power. Already 4,450 glow lamps and 30 arc lamps are set up, and there still remains 120 H.P. for the transportation of power. Of the latter, 50 H.P. are already disposed of, and the residue will soon be required, in consequence of the unusually favourable conditions proposed, so that the entire installation will soon be in full work.

If we look at the financial phase of the question, we see a surprising result. Deducting the 440 glow lamps and the 30 arc lamps for street lighting, the income of the town from the undertaking is :—

For 4,000 glow lamps at 12 candles average at 50 kreuzer per month, or 6 florins yearly	24,000 florins
For hire of 120 H.P. at 10 florins yearly	4,800 „
Total	28,800 „

But the town has to meet the following outlay :—

Management, working and main- tenance, according to the ex- perience of similar installations	18,400 florins
Interest on capital	26,000 „
Sinking fund and money necessary to be written off, including de- preciation at 0.5 and 5 per cent...	17,875 „
Outlay, total	62,275 „
Deduct returns	28,800 „
Deficiency	33,475 „

which the city has to charge to the account of public lighting.

Hitherto the city has paid for public lighting :—

Gas	8,600 florins
Petroleum, in outward radius	2,000 „
Total	10,600 „

The town will expend therefore in future more than three times as much for public lighting as heretofore. It must be remembered that the change has been from gas to electricity, which, under favourable circumstances, produces no increased outlay, and is sometimes even a saving. It must further be considered that Trient is by no means a wealthy city, and that it now raises 180 per cent. of the imperial taxation as a com-

munal tax. Surely, many a city may take an example and indulge in a luxurious system of lighting! But we must add that the estimate for the electric lighting of Trient was, originally, only 210,000 florins, and the abnormal cost of execution was by no means the intention of the Trient municipality.

### COMMUNICATIONS FROM AUSTRIA-HUNGARY.

[FROM A CORRESPONDENT.]

THE Vienna International Electrical Company has applied to the authorities at Buda-Pest for a concession to erect and work an electrical works for supplying electricity for illumination, the conveyance of mechanical power, and other industrial purposes. The company apply for the concession for 50 years, after which time the entire works are to pass gratuitously into the possession of the city. But it is open to the municipality to terminate the agreement after the lapse of 20 or 30 years, that is to say, after 20 years, on a payment of 20 per cent. above the valuation, or at the end of 30 years simply at the valuation. For the right of using the public streets to lay down the cable leads, the company would pay the municipality 3 per cent. of the gross returns. It is to be presumed that the capital of Hungary will at last come into the possession of electrical works.

In the Hungarian port, Fiume, proposals were requested for the erection of a mechanical elevator at the railway station. Electrical motors are proposed, which are to be supplied with current from the works projected for the illumination of Fiume.

At present telephone central stations are being erected in the cities of Fiume, Raab, Oedenburg, and Esseg. Several extensive landowners are also connecting the buildings on their possessions with telephonic sets. The company, for regulating the river Raba, is doing the same, and is connecting the various stations on their regulating line by telephones constructed by Egger and Co., of Buda-Pest.

The last weeks have been characterised by violent thunderstorms, especially in the mountainous parts of Austria, and several falls of lightning are reported.

At Marienbad the lightning struck repeatedly in two successive nights at various parts of the overhead leads of the electrical works. The machines were deprived of current after the strokes, but were not further damaged, and have since worked correctly. It is announced from Villach that in the night, between the 4th and the 5th of the current month, one storm followed another from 9 p.m. to 6 a.m. Flash followed flash, the thunder was unceasing, and the rain and hail destroyed the residue of the crops. Ten times the lightning fell in the city and suburbs. Two strokes followed each other in quick succession along the lightning rod of the tower of the parish church and destroyed the apparatus upon it and the one below it in the police watch-house, where the officer on duty was rendered unconscious. Another flash struck the house of General Six, tearing down the tiles and the timbers of the roof. Further flashes struck the railway bridge over the Drau, some trees, and an Alpine hut, which was burnt down. According to report, buildings were set on fire in the same night at Tarsis and St. Veil. The church-tower of Leopoldskirchen, which, like most of the towers in Corinthia, had no conductor, was burnt to ashes. On July 31st, two towers were fired by lightning at Lavamünd, and at Kolnitz two bells were melted and one shattered. In the afternoon two more storms burst over Villach. During the second a woman was killed. In consequence of the torrents of rain, the Drau has risen three metres and caused much damage.

The Hungarian Minister of Commerce has granted a concession for laying down the leads for the electrical works at Karanseles, which will be carried out with alternating current transformers at a tension of 2,000

volts. This is the first concession granted by the Hungarian Ministry for such an installation, and the conditions of the concession will be a standard for the erection of overhead leads of high-tension transformers.

The conditions prescribed are as follows :—  
1. The aerial leads must not be stretched too tightly. At 20° Centigrade they must not be strained above one-third of their total tenacity, and wires of less than 3 mm. in diameter must not be used.

2. The heating of the wires by the current must not exceed 20° C.  
3. The leads must be fixed upon rod supports in such a manner that the wires run at least two metres above the roof. If this is not possible, they must be conducted at least 6 metres above the roadway.  
4. Where lighting wires and telegraph wires cross each other, the former must be at least 2 metres higher than the latter, and due precaution must be taken to prevent these respective wires coming in contact.

# AN ACCOUNT OF SOME EXPERIMENTS UPON THE APPLICATION OF ELECTRICAL ENDOS- MOSE TO THE TREATMENT OF GOUTY CON- CRETION.

Presented to the International Medical Congress at Berlin by  
THOMAS A. EDISON, of New York.

HAVING ascertained that gouty concretions are in many cases medically treated with the aid of lithium salts taken internally, with the object of causing urate of lithium to be formed, dissolved, and excreted from the body; and being also informed that the difficulty met with in the treatment was in ensuring that the salts so administered should be absorbed into the system, it occurred to me that perhaps more rapid success might be obtained if the application were made externally, employing the well known principle of electrical endosmose to carry the lithium into the tissues. This method of operation appeared to offer considerable hope of success, because the lithium would be brought directly into the neighbourhood of the concretions and would thus be more likely to act promptly and effectively.

Electrical endosmose, as the name implies, is that property of an electrical current passing through a porous diaphragm between two solutions, in virtue of which one solution is mechanically transferred across the barrier. The current seems, in fact, to accelerate the diffusion which always takes place between solutions separated by a porous diaphragm, and at the same time acts in one direction, the solution being carried from the positive to the negative pole, from the anode to the cathode. A full description of the phenomenon is given in Wiedemann's "Die Lehre von der Elektrizität."

To test the possibility of causing lithium salts to pass in this way through an animal membrane, I made the following experiment:—

A glass funnel of 7.5 centimetres diameter at aperture was closed by a piece of sheep bladder 0.012 cm. thick, thus providing a porous diaphragm of 44 sq. cms. area. This funnel was inverted and filled with slightly acidulated water, and a platinum wire passing down the tube formed the negative electrode. The whole was then immersed about 1 cm. below the surface of a 2½ per cent. solution of  $\text{Li}_2\text{O}$ , contained in an evaporating dish above the bottom of which it was supported about 1.25 cms. Immediately after immersion, a second platinum wire forming the positive electrode was dipped in the dish, and a current of 150 milliamperes sustained steadily through the apparatus for 75 minutes. The funnel was then removed and emptied. Its contents were mixed with a solution of  $\text{NaPO}_3$ , and the mixture evaporated to dryness. The residue was then treated with water to dissolve the sodium salt and then left for 12 hours. The final precipitate was found to contain 0.5 gramme of  $\text{LiPO}_3$ .

The experiment was then repeated under precisely similar conditions except that no current was passed through the apparatus and diffusion only could be active in transferring the salt. The analysis in this case showed that 0.3 gramme of lithium phosphate was present, from which it was presumed that in the previous instance the current had increased the diffusion transfer to the extent of 67 per cent.

Finding the experiment succeed with a membrane, I next tried whether a healthy man, after being subjected to such a course of treatment as a patient suffering from concretions might be expected to undergo, would not give indications of the absorption of lithium in his excretions. In October, 1889, J. D., an active healthy labourer, aged 20, and of 140 lbs. weight, was operated upon in my laboratory. He sat in a chair and kept his hands immersed to the wrists in glass jars, one containing a solution of 2 per cent. lithium chloride with a platinum electrode, and the other containing a solution

of common salt with the negative electrode. The current passed through him was 4 milliamperes, which was as much as he could conveniently stand. This treatment was continued for about two hours daily during one week, the total time of application amounting to 11 hours. His urine was collected during that week, and tests were then applied to it. Using a particular spectroscope and method, it was found that a solution containing  $\frac{1}{40000}$ th part by weight of  $\text{LiCl}$  in water was just detectable by a faint red band in the spectrum. No such band could under these circumstances be discerned from the urine itself, but a condensation of all the week's urine reduced to the form of chloride gave a distinct band. An evaporation of  $\frac{2}{5}$ ths of the total quantity of this liquid yielded on analysis 0.22 gramme of lithium chloride, and it was therefore presumed that the whole amount of salt excreted was 0.55 gramme, corresponding to 0.09 gramme of metallic lithium, or equivalent to the removal of 2.43 grammes of uric acid.

I next tried the application of the method to a patient suffering from an acute and typical form of the malady, in December, 1889. This person volunteered to try the effect of the method. He was 73 years of age, and had lived an active healthy life until ten years previously, at which time, according to his own statement, he contracted the disease through sleeping in damp sheets. Concretions commencing continued to increase slowly until they assumed large proportions. All the joints, except the knees, were much enlarged by atheromatous concretions. A certain degree of venous congestion was visible in his face, and incessant pain had supervened in various parts of the body during the last few months, apparently from the pressure of the calculi upon the nerves. The joints of the fingers were almost obliterated by concretion.

The girth of the little finger of the left hand was, by careful measurement, 8.6 cms., that of the corresponding finger on the right hand even greater. There was great weakness and difficulty in walking, but the mind was clear, and intelligence unimpaired.

Treatment was commenced in the manner above described. The current generated from my laboratory 120 volt dynamo, passed through about 5,000 ohms resistance, and entered a jar containing an aqueous solution of lithium chloride, density 1.08, in which the patient immersed his left hand up to the wrist. His right hand was similarly immersed in a solution of common salt. The current, after passing through his body, left the latter jar by a negative electrode. It was found that he could stand 20 milliamperes without inconvenience, and this strength of current was steadily applied for six days during four hours daily. At the end of that time the girth of the left hand little finger was distinctly reduced to 8.2 cms.; the patient also experienced freedom from pain after the first day's treatment. He continued the treatment for two days more during the week following, and then the journey to and from the laboratory exhausted his strength. The finger girth, after 14 days from the date of commencing treatment, was 8.0 cms., a total reduction of 0.6 cm. This was estimated to represent a reduction of 3 cm. of concretion on this particular finger, whose form facilitated accurate measurement. His general condition, beyond the weakness resulting from unaccustomed journeying, was temporarily ameliorated.

From these experiments, I think it fair to conclude that satisfactory use can be made of the principle of electrical endosmose in such cases.

It should be mentioned that lithia was first tried in the bath solution, and given up on account of its caustic effects. Even an aqueous solution of 1 per cent. of lithia was found to blister the hands after some continued immersion. It would, therefore, have been necessary to employ a very weak solution, had its use been retained, with a correspondingly lengthened course of treatment, but time did not allow of. The chloride was used in the expectation that it would be decomposed within the cuticle during the act of endosmose by electrolytic action, or that, failing this, it would enter into a direct combination with the uric acid,

## NOTES.

**Voltaic Battery with Iron Electrode in Pure Water.**—The *Comptes Rendus* of the French Academy of Sciences for 1862, page 700, describes Gerardin's battery, in which the zinc is replaced by a mass of iron filings, and an iron bar inserted into said filings, both being placed in pure water. The other electrode is of carbon, and is placed in a porous cup containing a solution of perchloride of iron and nitro-muriatic acid. This is a pertinent reference for the d'Humy primary battery, as it fully discloses an iron electrode placed in pure water.

**Dynamos in Central Stations.**—We notice in the issue of *Industries* for August 15th, the first instalment of a paper by Mr. James Swinburne, on the "Coupling and Control of Dynamos in Central Stations." The subject, and its method of treatment, are alike interesting; there is plenty of room for an article of this description.

**The Telephone in the West Indies.**—The Spanish Minister of the Colonies has received authorisation to grant concessions for establishing telephonic communications in the Islands of Cuba, Puerto-Rico, and the Phillipines.

**The Spanish Atlantic Cable Again.**—Once more has this annual blossomed. Whether a crop of fruit will be obtained is another question. We learn that the Spanish Minister of the Colonies has again offered that hardy plant, the direct cable between Spain and the West Indies, to public tender.

**Private House Lighting.**—The lighting of the "Manor House," near Twyford, has just been completed for W. L. Beale, Esq. The installation consists of an eight horse Priestman's oil engine, Crompton dynamo, and 53 E.P.S. cells, with about 120 incandescent lamps, and shortly the current will be utilised to pump water for the house. It is hardly necessary to say that the light gives the greatest satisfaction. The work of the installation was carried out by Mr. W. V. Scott, under the instructions of B. R. Beale, Esq., of Messrs. Crompton and Co., Limited.

**Electric Lighting at Woolwich.**—As anticipated, the Woolwich Local Board of Health has given consent to the Woolwich District Electric Light Company for the lighting of the town by the electric light.

**Electric Lighting at Canterbury.**—The Canterbury Corporation has passed a resolution in favour of making application to the Board of Trade for a provisional order to supply electricity for public and private purposes in the City and Borough of Canterbury.

**New Spanish Cable.**—The *Official Gazette* of Madrid, under date of August 18th, publishes an official announcement inviting tenders for the construction and laying of cables between Tarifa and Tangier, Tarifa and Centa, Almeria and Melilla, and other Spanish possessions on the coast of Morocco.

**A New Use for Rubber.**—We learn that the municipal authorities of Brussels have decided to experiment upon the new compound called "caoutchouc macadam." A portion of the Boulevard Anspach is being paved with this material. The compound consists of a mixture of India-rubber and different kinds of stones, ground up together, and thus converted into a sort of cement by means of heat. The material is stated to be hard, elastic, and durable, and to be unchanged by either heat or cold. If the mixture possesses the properties claimed for it we should fancy that it would be pre-eminently suitable for running tracks, and lawn tennis courts.

**Electric Railway in Sweden.**—We have to chronicle the construction of an electric railway at Boxholme, Sweden. It is intended for the carriage of manufactured articles from the ironworks to the store-houses. The motive power is a 50 H.P. turbine, working two of Wenström's dynamos. This railway is, we believe, the first of its kind in Sweden.

**The New Thomson Dynamo.**—A communication from Prof. Thomson to the *Electrical World* gives some interesting facts concerning his new dynamo, described in our last issue. It will be remembered that the principal electrical characteristic of the machine was absence of hysteresis in any marked amount, while the construction adopted possesses the great advantage of requiring no revolving wire. The construction of the machine has actually been simplified, even beyond the point shown in our illustrations, so that it is exceedingly easy to construct and prepare. Several have already been built—most of them of similar size, and one of them for alternations as rapid as 2,500 complete reversals per second. The construction of the machine as a dynamo lends itself very easily to obtaining such high rates of alternation as are rendered highly desirable in certain classes of work. If the suggestion referred to some time since, of making transformers without iron cores, is ever carried out this new Thomson dynamo should come into play with beautiful effect. Of course, in a converter without iron, very high alterations are absolutely necessary to economical and efficient construction; but the advantages to be gained are great enough to make it a very interesting subject for experiment. In such case it should be noticed that any dynamo in which the magnetisation of a considerable mass of iron is reversed at each alternation is practically excluded from use, since hysteresis would rise to an enormous amount, while the present machine, from almost complete absence of hysteresis, is admirably fitted for the purpose. A 1,000-light dynamo of the new form has already been constructed, and is in process of testing. It has shown remarkably good results, and it is specially noticeable that the iron is free from heating, and the efficiency eminently satisfactory. A still larger machine is being planned, and there seems to be no good reason why the capacity may not be increased almost indefinitely.

**Electric Light and the Daily Press.**—Our bright little pink contemporary, we don't mean the *Sporting Times*, but the "*Globe*," a few evenings since had a somewhat superficial article on the subject of electric light in churches. It seems to think, and says, "The ladies are by no means unanimous in its favour, for it does not always add to the beauty of the complexion;" in this respect the writer of the roseate one's article appears to share the ignorance of the ladies when discussing the same subject, for at St. Jude's Church, of the illumination of which he is speaking, the lighting is to be by incandescence lamps of 8 candle-power and not by arc lights, which are well known to give a cold effect to the tone of even the most radiant faces. Again he says, "A church which is all glare from beginning to end—in every corner—is not acceptable to everybody;" just so! but we do not consider that glare is usually to be dreaded when 8 candle-power lamps are to be employed in a spacious building.

**A Trifling Request.**—Will some kind friend, who is not an editor, and who, therefore, may find time hang heavily on his hands, answer the following questions which an Indian subscriber has forwarded to us:—Could you inform me of what is the portable battery of four cells for electric lighting, by J. Pitkin, maker and patentee, made, and with what charged? In making a horseshoe magnet, what is the minimum distance the poles or ends should be apart? What would be the result or effect of their being brought very near, short of actual contact? If a Siemens' relay were fitted with larger slots or shoes, so as to extend, as it were, the whole length of the tongue, what advantage would there be, if any? In the differential system of duplex, double current, translation with Siemens' relays, does the want of insulation between the cores and the brass cylinder, and hence between the rest and working stops of the relay, and the cores when the tongue is either in the rest or working position, interfere with the efficiency of the relay in direct translation? How can the following fault be localised? A line is in contact with another which is worked in "closed circuit," and over which the testing station has no control, supposing a "loop" with another available line possible.

**Ryde Electric Railway.**—On the last Bank Holiday over 6,000 persons were carried along the electric railway on Ryde Pier.

**National Electric Light Association.**—The meetings commenced on Tuesday, and were to terminate yesterday. Among the papers read were the following, a selection of which will be given in a subsequent issue. "Electric Light as Supplied to Steam Railroads," W. H. Markland, Altoona, Pa. "Triple Expansion High-speed Engines for Central Station Work," E. F. Williams, Beloit, Wis. "Ferranti Station, London, England," Caryl Haskings, Lynn, Mass. "The Proper Care and Management of Alternating Currents," T. Carpenter Smith, Philadelphia. "Distribution of Energy by Alternating Currents and Transformers, and the Proper Method of Proportioning Conductors," A. H. Rohrer, Lynn, Mass. "The Proper Basis for Determining Electric Motor Rates," H. L. Lufkin, New York. "Actual cost of furnishing Arc Lighting (1,200 C.P., and 2,000 C.P. Lamps) under the Best Possible Conditions," J. C. Ayer, St. Louis. "Municipal Ownership of Electric Lighting Plants," M. J. Francisco, Rutland, Vt. "Accidents in Electric Lighting Stations and Plants," Prof. Charles R. Cross, Boston. "Care and Labour in Electric Light Stations and its Value," A. J. DeCamp, Philadelphia. In addition to these papers, various reports were to be considered.

**The Joke of the P.O. Electrician.**—Speaking of the recent scientific joke, our contemporary, the *New York Electrical World*, says:—The principal London electrical papers escaped unscathed, but the small fry, and some large enough to know better, were with one accord taken in. As might have been expected, when it transpired that the supposed invention was a hoax, the victims were somewhat demoralised, and while some of them preserved a discreet silence, others waxed wroth and growled out protests.

**The Lane-Fox Patents.**—In connection with this a meeting was held last week of various firms interested, and it was resolved to form an association on the lines of the circular published in the *REVIEW* on August 8th.

**The Volta Electrical Company, Limited.**—Creditors of the company are to send their names and addresses of their solicitors, if any, and particulars of debts and claims to Mr. Thos. Browett, Sandon Engine Works, Salford, Manchester, the liquidator, on or before 19th September next, or to be excluded from any distribution made before such debts or claims are proved.

**An Extraordinary Robbery.**—A correspondent of a daily paper states a most extraordinary case of robbery in Paris. Six thousand metres of cable had disappeared from the Champ-de-Mars, while at the other end of the city, in the Avenue Daumesnil, near Vincennes, an exactly similar length of wire was missing. Furthermore, an inspector from the Post Office discovered that the cable between the Rue de Grenelle and the Rue de Villejust, as well as that connecting the Place de la République with the central markets, had been cut in different places. It appears that all this damage—which caused much delay, inconvenience, and complication—was done by two professional excavators or "navvies," named respectively Chartier and Haurant. These men, who probably had assisted in putting down the wires, were in the habit of carrying on their operations at night, when they descended into the drains or cuttings with dark lanterns, and carried away both the cables and their environments. The principal delinquents were each condemned to 15 months' imprisonment, while the receivers were sent to gaol for shorter periods—a salutary example being thus made of the destroyers of telephone wires, and one which, it is to be hoped, will prevent other ingenious persons from endeavouring to imitate the mischievous deeds of the scientific "navvy" and his colleague.

**Telephone Monopoly in Germany.**—The well-known Telephone Manufacturing Company, Actien Gesellschaft, Mix and Genest, has been successful in an action brought against the Government as to the building and maintaining of telephone lines. Previously the German Post Office succeeded in prohibiting all telephone installations erected by private companies. By the spirited action of the company this state of things has been entirely altered.

**Car Companies at Chicago.**—Two new car companies have been started at Chicago—the Columbia Street Car Manufacturing Company, capital, \$100,000, and the United States Electric Car Company, for the manufacture of electric cars, capital \$3,000,000.

**Fire at the Edison and Swan Factory.**—A fire broke out in the depositing rooms of the Edison and Swan Electric Factory, at Ponder's End, on Tuesday morning. This portion of the factory is divided from the remainder by a thick party wall of great height. The cause of the fire was the ignition of some benzoline used in the work. The fingers of the girl using the benzoline were hurt, but about fifty other girls, to whose benches the fire quickly spread, were got out of the place uninjured. The local fire brigade attended, but their efforts were confined to preventing the flames from spreading. They thus saved the remainder of the premises, but the depositing building was destroyed. The amount of the damage is not known, but it is very considerable.

**Percussion Cap Lightning Arrester.**—In a recently made American arrester ordinary percussion caps are employed to break the arc which so often follows the static discharge. The heat produced by the current when the arc is formed explodes the cap, thus blowing out the arc. It is said to work admirably in practice.

**Fan Motors.**—During the recent hot weather in America motors have been largely used for propelling fans.

**Tenders for Lighting.**—For lighting the parish of Heavitree with gas or electricity, for three years from 24th October. Full particulars from G. Havill, jun., Fore Street, Heavitree. Tenders to be deposited by the 30th. Tenders wanted, by 1st September, for lighting Kinsale, Ireland. Mr. Hegarty, Town Commissioners' Office.

**"Manganese-Steel."**—Mr. Hadfield, of the Hecla Works, has been awarded a gold medal by the Société d'Encouragement pour l'Industrie Nationale for an entirely new alloy of iron and manganese.

**The Claims of Primary Batteries.**—A company is now engaged in America exploiting a certain form of primary battery, and in its descriptive circular the main object appears to fascinate the gullible public by quoting the historical details of Jacobi's boat experiments on the Neva more than 50 years ago, and Professor Page's car trip in 1851. The climax is reached, however, when we see that the "eight horse-power machine on our car will develop more actual mechanical horse-power (as operated by the primary batteries) than the combined power of two 10-H.P. motors as now operated by the several dynamo methods." The example of George Washington is evidently emulated by but few inventors in the States.

**Award.**—A Gold Medal has been awarded by the Société d'Encouragement pour l'Industrie Nationale to M. Ducretet, of Paris, for his services to science and industry, amongst which may be noted a Wimshurst induction machine of great power and an ingenious device for reproducing Professor Elihu Thomson's experiments in connection with electro-dynamic repulsions and rotations.

**Alternating Currents Doomed.**—The Société Industrielle du Nord de la France has awarded a silver medal to M. Lafargue, for a note on the distribution of electric energy by alternating currents. M. Lafargue is of opinion that alternating currents will, sooner or later, fall into disuse.

**Electromotors and Weaving.**—MM. Chaize frères, weavers, of St. Etienne, have been awarded a gold medal by the Société d'Encouragement pour l'Industrie Nationale for an ingenious application of electromotors, which they have been using in their workshops for some time. The Société has also conferred a similar honour upon M. Monchère for an ingenious application of electricity to the reeling, weighing, and making up into balls, of silk and similar woven fabrics. A silver medal of the same Société has been awarded to M. Radiguet, of Paris, for his electric knitters for use in the hosiery trade.

**Obituary.**—*Electrical Industries* of America says:—Mr. James W. Queen, founder of the celebrated house of Jas. W. Queen & Co., 924, Chestnut Street, Philadelphia, died July 12th, at Cresson, Pa., where he was visiting in the hope of receiving benefit from the mountain air. Mr. Queen had reached the good age of 78 years. His name occupies a prominent place in the business records of Philadelphia, and most of the high class English and American houses were at one period represented by him in Philadelphia. His integrity was beyond question, and no one enjoyed a better reputation.

**Electric Lighting of Mines.**—M. Le Compte Gerson has presented the electric mining lamp, Stella, to the Academy of Sciences.

**Electric Lighting of the City.**—A Committee of the House of Commons confirmed the two provisional orders, granted to the Brush Electrical Engineering Company and the Laing, Wharton, and Down Construction Syndicate, for lighting the City. The area to the east of the Mansion House, Princes Street, and Moorgate Street is assigned to the Laing Construction Syndicate; and the area to the west of those points, as far as, and including, the north side of St. Paul's Churchyard, is assigned to the Brush Electrical Corporation. The orders have now been sanctioned by both Houses of Parliament.

**Cable Testing.**—Mr. C. H. Gray, of Silvertown, writing too late for our correspondence columns, says:—"The method described by Cuthbert Hall for localising faults, is practically the same as I employed eight or nine years ago at Persan for the same purpose, the only difference being that, instead of insulating the trough as he has done, I insulated the stand on which the hobbin containing the wire to be tested was supported. There is practically no difference between the methods, and both are simply improvements on Warren's old method of localising faults in core. The only advantage I can see in my method seems to be that in actual practice I used a long trough, and was thus able to travel at a considerably higher speed than could be attained with the short trough used by Cuthbert Hall. They are still, I believe, using the above method at Persan for localising faults in common bell-wire core."

**Gas and Electricity.**—Presiding at the half-yearly meeting of the Liverpool United Gas Light Company, on Tuesday, Mr. Edward Lawrence stated that so far as the application and use of electricity went, up to the present time he saw nothing to cause uneasiness to the proprietors of gas stock. It was quite true the consumption of electricity in Liverpool was increasing, but at the same time the consumption of gas had increased by 2 per cent., and he thought they might safely conclude that with other uses being found for gas the consumption would continue to be extended, while the use of electricity would also be increased.

**Foreign Wire Industry.**—The Italian Metallurgical Company is very busy just now with orders for electric wires.

**Bimetallic Conductors.**—The Administration of Posts and Telegraphs, France, is about to make a trial with the Durand system of bimetallic telegraph and telephone wires, composed of red copper with steel cores.

**The Manufacture of Electric Motors.**—As showing the great demand for motors, it is stated that the C. and C. Motor Company, of New York, have sold during the last six weeks 2,000 motors, which is equal to the sales of any previous year.

**Fire Office Rules.**—Major Flood Page, in a lengthy letter to the *Times* of yesterday, discusses the various fire rules of insurance companies. He had considered over twenty sets of rules, and came to the conclusion that the Phoenix Rules were the most acceptable in every way.

**Martignoni Disc Cutting Tools.**—The Machinery and Hardware Company of London, having obtained the sole right to manufacture the Martignoni patent disc cutting tools for lathes and general machine tools, have been demonstrating their value by showing them in actual work at their own show-rooms. These tools are expected to create quite a revolution in the turning and machine tool trade, as they are calculated to effect a saving of both time and material. They do away with the necessity for reforging or "fettling" tools, as the emery-wheel, in the hands of a boy, is sufficient to put a new edge on the tools in a few moments. There is no waste steel, and as vibration is avoided the machine can be run at a higher speed. No doubt many of our readers will be glad to have their attention called to this useful novelty, of which further particulars may be obtained on application to the company

**New Insulated Wire.**—We extract the following from the issue of the American *Electrical Engineer* for August 6th:—"The insulation of the American Circular Loom Company's wire, however, is not braided, but woven on by means of circular looms of improved type, the invention of Mr. Charles T. Stetson. The cotton is No. 12 single, and is twisted together at the factory in as many ply as is necessary for the size of wire to be covered. The twisted cotton is then put in the loom, which works exactly the same as looms for weaving flax fabrics, so many bobbins forming the woof, and so many bobbins being so shaped as to fit the shuttles which circulate round the loom and forming the warp. The looms are about four feet in diameter, and the mechanism is extremely simple and interesting to the eye of a mechanic. The shuttles move round very rapidly, the woof being moved up and down by means of eccentric rods on revolving discs, so that the warp passes below one thread and above the next one. When completed, the woven insulation is very hard and firm, and has the appearance of a canvas jacket, like a piece of sailcloth around the wire. The wire is then taken to the compounding house, where a special compound is forced into the cotton insulation by a secret process so effectually that every fibre of cotton is thoroughly impregnated. It is then polished and finished and wound on drums for shipment. When finished, the insulated wire has a peculiarly tough finish, and is particularly capable of withstanding a large amount of abrasion, and is at the same time as waterproof as any line wire with cotton fibre in the insulation can be, and is to a very extraordinary degree fireproof."

**Microphonic Phenomena.**—The paper which Mr. Tanner has courteously sent to us for publication on microphonic effects is exceedingly interesting, and will doubtless be appreciated by everybody engaged in telephonic pursuits. This gentleman has also unearthed the description of a battery, appearing amongst our "Notes," which anticipates the famous D'Humy cell, although the same feat has been previously accomplished by others.

**Submarine Telegraphy Threatened.**—It seems scarcely possible that the advent of electric railways should threaten a serious disturbance to signalling through long cables; yet the experiences of Mr. Cuttriss point to the possibility of grave complications arising from the proximity of heavily charged conductors interfering with telegraphic signals on the Atlantic cables. Probably, if this kind of thing develops so as to seriously interfere with business, an edict will be issued to prohibit any electric car running within a given distance of important telegraph lines, unless carrying its own motive power—in other words, it will be another argument in favour of accumulators.

**Good News for "Okonite" Shareholders.**—The Okonite Company, of New York and London, manufacturers of okonite insulated telegraph, telephone and electric light wires and cables, has completed its new factory at Passaic, N.J. It is an imposing three-storey brick building and employs 400 hands. The company is turning out on the average of 60 miles of okonite insulated wire per day, and is still a month behind its orders. It recently received an order for 1,000,000 feet of wire from the Chicago Edison Company, Chicago, Ill.

**Electricity and Poetry.**—There is a tendency among the Americans to fall into poetry when considering things electrical. Dr. Oliver Wendell Holmes has celebrated the electric car in a somewhat lengthy poem. He identifies the trolley poles as "witches' broomsticks," and, referring to the sparking, he says "we may see the gleam of her wicked eye."

**Electropathic Quackery.**—The *Hospital Gazette* says:—"It is high time measures were taken to stop the serious imposition practised on the public by a large body of men who—notwithstanding their professed ignorance of the first principles of anatomy, physiology, pathology, therapeutics, and electricity—set themselves up as experts, and largely advocate their worthless patents to credulous and easily-duped individuals, the majority of whom possess highly neurotic temperaments. Towards the suppression of such nefarious practice the press can exercise a mighty influence, and acquaint the public with the various ways they are being put upon by these tricksters and would-be benefactors to suffering humanity. The ELECTRICAL REVIEW, we are pleased to see, has taken a prominent lead in this suppression, and formed a committee for this purpose. It is to be hoped other journals, but more especially those which are circulated largely amongst the public, will imitate the example set them, and boldly denounce the frauds which are being daily practised on us. In taking such steps these journals will not only benefit society, but will place a salutary and lasting check on the methods and practices which must seriously impede the advancement of one of our most important sciences. Unfortunately, however, the majority of newspapers aid and abet the electrical quacks by publishing their advertisements and reports of alleged 'wonderful cures.'" The only remark we desire to make on this expression of opinion from the *Hospital Gazette* is, that the ELECTRICAL REVIEW is quite unconscious of the formation of any committee.

**Street Names Read at Night.**—It is said that the inspector of streets of St. Louis has adopted a novel method of marking the names of streets, so that the darkest night will not render the way difficult to find. The names of the streets are painted upon the electric light globes, and the shadow resulting throws the name upon the ground so plainly that it can be read 50 feet away. The letters on the globe are three-quarters of an inch, and the shadow is five feet wide. An arrangement of this nature would be a welcome one elsewhere.

**Mr. Edison as a Medical Electrician.**—The article which we print on page 213 shows Mr. Edison in a new character, one, indeed, in which we trust he may shine as brightly as he has hitherto done in the application of electricity to the industrial arts. The subject he has taken in hand is one of great importance, and will be duly appreciated by those who have suffered various degrees of torture from an excess of uric acid.

**Submarine Cables.**—The table of interruptions and repairs to submarine cables during 1888–1889, which we publish on another page, will be found of service to those interested in their manufacture, laying, and repair, as well as to the various telegraph companies. We expect that in the near future this table will be considerably elongated.

**Electric Lighting Statistics in North America.**—The following figures, which we cull from *Electrical Industries*, show to what enormous proportions the central station electric light industry has grown in North America. The number of stations is given as 1,379; the arc lamps in use as 137,441; the incandescents of 16 candle-power as 1,590,967; the engine capacity 356,755 H.P., and the capital invested as \$118,758,500.

**"Beneficent Murder."**—The *D.T.* has thrown open its columns, and the subject now discussed in a general way is the death of Kemmler. Mr. Buchanan is holding forth against what he calls cowardly experiments.

**Woodhouse and Rawson.**—We are informed that Woodhouse and Rawson United, Limited, have been awarded a silver medal for their show at the Exhibition of Fire and Life saving apparatus now being held at Amsterdam.

**Electricity and Ballooning.**—Electrical motors for use in ballooning are being manufactured at the Meudon military workshops on the plan invented by M. Renard. The importance of the discovery is said to be such that the details are kept strictly secret, although probably this is a greatly exaggerated version of the real facts.

## NEW COMPANIES REGISTERED.

**Nonpareil Electric Syndicate, Limited.**—Capital, £6,000, in £10 shares. Objects: To adopt an unregistered agreement of the 8th inst., between James Tarbottom Armstrong and Joseph Mason, of one part, and W. J. Smith (for this company), of the other part, relating to the purchase by the company of the letters patent granted to Joseph Mason for "a new or improved automatic coin-freed machine for giving electric shocks;" No. 1757, dated 11th October, 1889. Signatories (with one share each): J. Cunningham, 1, Maude Villas, Peckham; W. J. Smith, 29, Somerfield Road, N.; T. Sanders, 12, Dinsdale Road, Westcombe Park, S.E.; J. W. Jenner, 34, Millbank Street, S.W.; J. Willpress, 37, Hubert Grove, Stockwell; D. Capern, 139, Grosvenor Park, Camberwell; C. B. Woods, 37, Markham Square, Chelsea. Registered, 13th inst., without special articles, by A. R. Fowler, 2, Victoria Mansions, Westminster.

**Gordon Electric Traction Syndicate, Limited.**—Capital, £2,400, in £10 shares. Objects: To purchase the invention of John Gordon of a system of electric street car traction, provisionally protected, 5th May, 1890, No. 6,083. To purchase all future inventions of John Gordon suitable to the better application of the said invention. To develop the working of the invention, and in particular to carry on experiments at the works of Messrs. Merryweather and Sons, at Greenwich and elsewhere. Signatories: John Gordon, 13, Nettleton Road, New Cross, electrical engineer, 1 share; Wilhelm Luttge, 21, Lime Street, 14 shares; A. F. Koehel, 6, Fenchurch Street, 5 shares; J. C. Merryweather, Greenwich, 10 shares; E. Pascoe Williams, Blackheath, 10 shares; J. M. V. Money Kent, 34, Victoria Street, S.W., 10 shares; H. R. Goring, 17, Leadenhall Street, 10 shares. The signatories are the first directors, and Mr. Gordon is appointed managing director. Registered, 13th inst., by Gilbert Robins, 11, Pancras Lane.

**Trujillo Railway (Peru), Limited.**—Capital £500,000, in £1 shares. Objects: To acquire, construct, equip and maintain railways, tramways, telegraph and telephone lines in Peru, and to acquire the rights of the Peruvian Corporation, Limited, under any concessions or contracts relating to such means of communication. Also to construct electric lighting works, and to acquire, use, and provide steam, electrical, hydraulic or other power. Signatories (with 1 share each): C. L. Smiles, J. R. Yates, 15, Bedford Row; W. H. Rawle Judd, 33, Liverpool Street; N. G. Hill, 40, Counters Road, Kentish Town; T. J. Mason, 22, Lorrimore Road, S.E.; W. F. Symonds, Oak Lea, Lordship Lane; F. W. Binyon, Chichester Road, Croydon. The subscribers are to appoint the first directors. Qualification, £100 in shares or stock. Remuneration—chairman, £200 per annum; other directors, £150 per annum. Registered 14th inst. by Smiles, Ollard and Yates, 15, Bedford Row. Registered office, 66, Old Broad Street.

**Vaughan Sherrin Electrical Engineering Company, Limited.**—Capital £25,000, in £5 shares. Objects: To manufacture and supply electric motors, generators,

tricycles, bath-chairs, boats and machines, either wholly or partly propelled or worked by electricity upon any system whatever, and to carry on the business of electrical and mechanical engineers. Signatories (with 1 share each): E. H. Roberts, 85, Rushmore Road, Clapton; H. Floodgate, 123, Pall Mall; Henrietta Sherrin, 19, Duncan Terrace, N.; H. H. Paice, 81, Lydner Road, N.; J. H. Dempster, 59, Abbey Street, Bermondsey; T. J. Edwards, 18, Standard Street, Newington; Miss Ellen Mary Simmonds, 19, Duncan Terrace, N. Mr John Vaughan Sherrin is appointed managing director, at a salary of not less than £300 per annum. The minimum remuneration of the ordinary directors is £400 per annum. Registered 16th inst. by Lowless and Co., 26, Martin's Lane, E.C.

## OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Thornebury Miner's Safety Lamp Company, Limited.**—An agreement of 30th ult., filed 31st ult., between James Thorne, of 85, Gracechurch Street, and the company, is supplemental to an agreement of 30th April and to an agreement of 20th May. The latter of these provided for the allotment of 15,000 fully paid shares of £1 each in part payment of the sum of £25,000 as purchase price for the British patent, No. 2779, of 1889. The said shares have been allotted, and sums of £2,500 and £1,960 have been paid in cash, and there now remains £5,540, and in settlement of this amount the present agreement provides for the allotment of fully paid shares.

**Dick, Kerr & Co., Limited** (engineers, electricians and contractors for railways, tramways, and other undertakings).—An agreement of 31st May, filed 20th June, provides for the purchase of the business carried on by Frederick Mannelle and John Kerr at 101, Leadenhall Street and at Kilmarnock, Ayrshire, under the style of Dick, Kerr & Co. The consideration is £115,000, payable £35,000 in cash and £80,000 in fully paid shares. An agreement of 6th June confirms the above.

**Allen, Everitt and Sons, Limited** (metal manufacturers, wire drawers, and electrical engineers).—An agreement of 5th June, filed on the 17th June, provides for the purchase by the company of the business carried on by Allen, Everitt and Sons at the Stephenson Works, Birmingham, and in London. The purchase consideration is £223,000, payable £132,000 in cash, £26,000 in £5 per cent. debenture stock, £33,000 in fully paid £6 per cent. cumulative preference shares, and £32,000 in ordinary shares, credited with £8 as paid up.

**Eastern and South African Telegraph Company, Limited.**—At an extraordinary general meeting of the shareholders in this company, held at Winchester House on the 17th ult., the following resolution was passed:—"That Article 100 of the company's articles of association be altered by striking out therefrom the word 'inclusive,' and inserting in lieu thereof the word 'exclusive.'" The resolution was confirmed on the 1st inst., and duly filed on the 7th inst. The article referred to the directors' remuneration of £1,200, inclusive of the amount paid to the managing directors, but which now stands exclusive of such amount.

The annual return of this company, made up to the 31st ult., was filed on the 13th inst. The nominal capital is £600,000 in £10 shares, the whole of which are taken up and are fully paid.

**Exeter Electric Light Company, Limited.**—The annual return of this company, made up to the 5th inst., was filed on the 11th inst. The nominal capital is £20,000, in £10 shares; 915 shares are taken up, and upon 780 of these the full amount has been called, and £2 per share has been called upon two

shares, the remaining 133 shares being considered fully paid up. The calls paid amount to £7,634, and unpaid to £186.

**Electric Date and Time Stamp Company, Limited.**—The annual return of this company, made up to the 30th ult., was filed on the 11th inst. The nominal capital is £121,000, divided into 100,000 ordinary and 21,000 deferred shares of £1 each. There are 6,893 ordinary and 21,000 deferred shares taken up, 25,500 been considered fully paid. Upon 2,393 ordinary shares the full amount has been called, the calls paid amounting to £1,824 5s., and unpaid to £568 15s.

**Column Printing Telegraph Syndicate, Limited.**—At an extraordinary general meeting of this company, held at 5, New Bridge Street, on the 30th June, it was resolved:—"That the capital of the syndicate be increased to £25,000 by the creation of 300 new shares of £50 each." The resolution was confirmed on the 16th ult., and was duly filed on the 8th inst.

The annual return of this company, made up to the 12th of August, was filed on the following day. The nominal capital is £25,000 in £50 shares; 171 shares are taken up, and of these 100 are considered as fully paid. Upon 71 shares £18 15s. per share has been called up and paid, the calls paid amounting to £1,331 5s.

**Mutual Telephone Company, Limited.**—At an extraordinary general meeting, held at the Memorial Hall, Albert Square, Manchester, on the 21st ult., the following special resolution was passed, viz.:—"That the articles of association of the company be altered in manner following: (a) In Article 99 the word 'ten' shall be substituted for the word 'six.' (b) The following article shall be substituted for Article 100, namely: 'The directors may, with the authority of the company in general meeting, take from the said reserve fund in any year such sum as the directors may think it desirable to apply towards payment of dividends on the shares, provided that in no case shall the dividends on the shares exceed 10 per cent. per annum on the amount paid up or credited as paid up thereon.' The original Article 99 relates to the payment of dividends not exceeding 6 per cent. per annum, and Article 100 authorises the directors to take from the reserve fund such sum as may be required to make up 6 per cent. per annum dividend. The above special resolution was confirmed on the 7th inst., and was duly filed on the 11th inst.

**Venezuela Telephone and Electrical Appliances Company, Limited.**—The statutory return of this company, made up to the 29th ult., was filed on the 15th inst. The nominal capital is £70,000, in £1 shares, the whole of which are taken up. 56,756 shares are considered as fully paid, and upon 13,244 shares 15s. per share has been called up. The calls paid amount to £9,544, and unpaid to £389. Registered offices: 37, Lombard Street.

**Institute of Medical Electricity, Limited.**—The office of this company, formerly at 24A, Regent Street, is now situate at 35, Fitzroy Square, W.

**Rastrick and Son, Limited** (chemists, opticians, and electricians).—The registered office of this company is situate at 7, King's Terrace, Southsea.

## CITY NOTES, REPORTS, MEETINGS, &c.

### The Petroleum Engine Company, Limited.

The report of the directors, for the year ending June 30th, 1890, states that:—

The progress of the company during the past twelve months has not in some respects been so rapid as the directors could have wished, but it is hardly necessary to point out that in developing an entirely new motive power, time is required to establish

sufficient confidence to secure orders freely from the general public.

The steady progress which has been made up to the present time is shown by the fact that the royalties received prior to June, 1888, amounted to £18, while the royalties received for the year ending June, 1889, amounted to £559, and the royalties received for the year ending June, 1890, amounted to £1,035.

Amongst orders recently received, many instances could be given where consulting engineers and others have been watching the working of the engine during the past 18 months before taking upon themselves the responsibility of recommending its adoption.

A considerable number of repetition orders have been received during the past 12 months, and an engine lately supplied represents the sixth order from the same purchaser.

The Priestman engine has recently been adopted by the Crown agents for the Colonies, the Norwegian and Egyptian Governments, and the Trinity House. The Northern Lighthouse Board, after making prolonged tests with three 5-horse-power engines supplied for a fog signal station, have given a further order for three engines of the same size for a second station.

The Royal Agricultural Society offered special prizes this year for light portable motors, arranged in two classes—firstly, for steam and hot air; and secondly, gas and oil engines. The first and only award in the second class was given for the Priestman engine, and the *Times* newspaper of June 23rd says:—"The first prize of £30 was awarded to Messrs. Priestman Brothers, Limited, of Holderness Foundry, Hull, for their well-known portable oil engine, to whom we believe the silver medal of the society has already been awarded. This engine is most economical in working, costing less in this respect than any other motor in either class."

Mr. Alderman Bailey, ex-President of the Manchester Association of Engineers, who read an interesting paper on the subject of "Canal Boat Propulsion," after tracing the history of steam propulsion from the first application of steam in 1799 down to the present time, adds:—"The Manchester Ship Canal Company, for the Bridgewater narrow canal, has recently purchased two Priestman's patent double-cylinder 10 horse-power vertical oil engines, with bevelled wheels, frictions, shafting, bearing, propeller shafts, stern tubes, and propellers. The engine was guaranteed to work with an expenditure of oil not exceeding 13½ pints per hour. On trial trips made, the expenditure was 10 pints per hour."

It is satisfactory to note many facts which indicate that the habitual distrust of new mechanical and scientific inventions is gradually yielding to the numerous demonstrations of the complete adaptability of the Priestman oil engine to the diverse purposes for which it has been brought into actual use, and a progressive increase of sales is confidently anticipated.

The amount of royalty paid by the licensees during the 12 months does not by any means represent the royalty on the whole of the engines sold up to the 30th of June last, as by the terms of the agreement, royalty is only payable to your company after the engine itself has been paid for.

The income and expenditure account shows a balance in favour of the company of £440 14s. 7d., which the directors recommend shall be carried forward to next year's account.

The retiring directors are Messrs. Henry Pawson and Ernest Moreton, who offer themselves for re-election. The secretary has received a notification from Mr. Septimus Gibbon, of 36, Finsbury Pavement, London, E.C., that he intends to offer himself as a director.

### General Electric Company.

The statutory general meeting of the shareholders of the General Electric Company, Limited, took place on Tuesday at the offices, 71, Queen Victoria Street.

Mr. Gustav Binswanger (the chairman of the company), who presided, stated that the business of the company was divided into three departments—electric lighting, electric bells, and the works at Manchester. The result of the trading was that they were able to recommend a dividend of 15 per cent. on the preference shares, and of 7½ per cent. on the ordinary shares, carrying, at the same time, a sum of £637 to reserve. This result must be considered extremely satisfactory, inasmuch as the earning power of the company upon the actual capital invested was more than 25 per cent. per annum. The business was continuing to show a very substantial increase, and as the winter was the best time for a business of this description, they had every prospect of being able to double the returns. The chairman concluded by moving the adoption of the report and accounts.

Mr. Myerstein seconded the resolution, which was unanimously agreed to, and the dividends as recommended were also declared.

Mr. T. J. Seel was re-elected auditor of the company.

Mr. Hess proposed, and Mr. Goldschmidt seconded, a vote of thanks to the chairman and directors, and the meeting separated.

### TRAFFIC RECEIPTS.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending August 16th, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,718.

## SHARE LIST OF ELECTRICAL COMPANIES.

## ELECTRICALLY HEATED TREVELYAN INSTRUMENTS THAT CAN BE USED AS MICROPHONES.

By A. M. TANNER.

IN my researches concerning the uses of carbon for electrical purposes I was at once struck with the great similarity certain types of Trevelyan instruments bear to the microphone, or that form of telephonic instrument, in which loose contacts of solid or hard carbon are employed for regulating the tension of the current in a closed electric circuit.

In Poggendorff's *Annalen der Physik und Chemie*, for Vol. 104, page 413, appears an article by Paalzow concerning some phenomena of motion in the closed circuit of a galvanic battery. It is here stated "that when a thin sheet of platinum is placed upon a copper plate that is connected with one pole of a battery of four Bunsen elements and a piece of carbon in the form of a half ring is placed upon the sheet of platinum, a cavity in the free end of the carbon receiving a drop of mercury, then a regular rocking motion of the carbon takes place when a platinum wire led into the mercury is connected with the other pole of the battery. The arrangement of parts for carrying out the experiment is illustrated by fig. 1, in which *a* is the copper plate, *b* the sheet of platinum, and *c* the carbon.

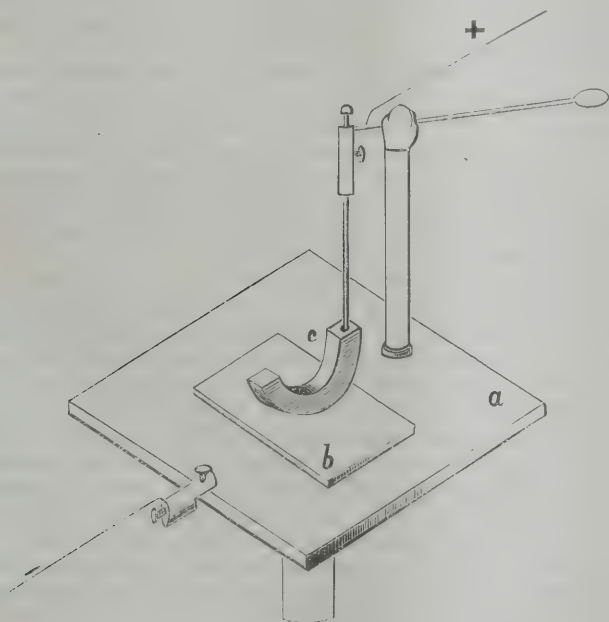

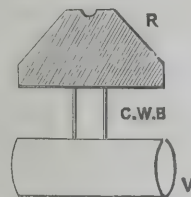

FIG. 1.

From experiments to determine the most favourable presentation of this phenomenon it was at once ascertained that sheet platinum such as is ordinarily used in Grove batteries, was best adapted for the purpose, and that very thin sheet brass and copper caused the phenomenon to appear in a weaker form, while the thinnest plates of other metals did not show it at all. When the metals were soldered to a copper plate of considerable thickness, then in the case of platinum the vibratory motion of the rocker was observed after the latter had remained a long time upon the platinum and sparks had passed. The rocker must be made of good conductivity such as is used in Bunsen elements and for the production of the electric light; wood carbon was not moved at all. Simultaneously with the movement of the rocker the passage of sparks between the carbon and platinum plate was observed, and when the motion of the rocker grew so violent that the platinum wire passed out of contact with the mercury, sparks were also observed between the platinum wire and mercury. Before the rocking took place, an elevation of the carbon always occurred, as if it were attracted by the platinum wire, and frequently there was only an

elevation of the carbon and no regular movement at all."

After the foregoing description, the experimenter discusses the probable cause of the rocking motion of the carbon, and says it cannot be attributed to repellant action; experiments disproved this theory, since the rocking movement did not take place with all metals. Then it is stated that it might also be due to the passage of the spark between the carbon and platinum which caused a hurling of the carbon particles with such a force as to produce the working movement; this theory was, however, also disproved by experiments.

Then Paalzow continues and says: "It can be shown, however, that the heat which is developed at the contact point by the passage of the spark, produces a change of form of the platinum plate, which necessarily must cause a movement of the carbon. When the rocker, or even a flat surfaced piece of carbon was placed on the platinum, then a raising of the edges of the platinum was observed during the passage of the spark." Paalzow then arrives at the conclusion "that at the point where the platinum is nearest the carbon, a spark passes across, and at the same time an unequal heating and change of form of the platinum takes place, so that the carbon is thrown out of balance, whereupon the passage of the spark is transferred to some other point, followed by another movement of the platinum and carbon. If the platinum surface is even, then the passage of the spark will take place where the carbon presses the platinum with the most force, so that upon the change of position of the carbon, the passage of the spark must again take place where the carbon touches the platinum. In Poggendorff's *Annalen*, vol. 105, page 620, Rollman calls attention to the fact, that as early as 1850, he described a Trevelyan instrument, moved by the galvanic current, in the *Jahresberichte des naturwissenschaftlichen Vereins in Halle*, page 189. This journal, consulted by me, states that it is known that the Trevelyan instrument is operated by the heating of the "rocker" or the "bearer." If both are allowed to remain cold, the sound can also be produced by passing a galvanic current through the in-

R, rocker; C.W.B., copper wire bearers; V, vice.

FIG. 2.

strument. The explanation is easy. The current will not produce a perceptible raising of the temperature of the massive rocker or bearer, but will cause a heating at the two points where they touch each other. What follows can be easily understood. I obtained sounds with bearers and rockers made of copper, and with a brass rocker and iron bearer connected with two Bunsen or Grove elements. The idea of operating the instrument in this manner is due to Prof. Hankel." In the article in Poggendorff's *Annalen*, Rollman says that all materials that are good conductors of electricity may serve for the carrier and rocker, provided the proper shape is given them at the contact points. Then he says that he experimented with rockers of brass, steel and gas carbon, and maintained the same in a state of permanent vibration upon bearers of gold, platinum, silver, copper, brass, nickel, German silver, iron, steel, zinc, cadmium, tin, lead, antimony, wismuth, aluminium and gas carbon.

Referring to the carbon rocker he says it was a roughly cut piece of gas carbon of a prismatic form (6 inches long, 1 inch wide and 1½ inches thick), provided with a handle. The bearers were by reason of the form of the rocker worked out into points and stretched in a screw clamp as was already done by Tyndall and Seebeck.

In order that this paragraph of Rollman's description

can be easily understood, I have consulted the published experiments of Tyndall and Seebeck, concerning vibrations and tones produced by the contact of bodies having different temperatures. It may be well to state here that neither proposed the use of carbon rockers and bearers. Tyndall's experiments are found described in the London, Edinburgh and Dublin Philosophical Magazine for 1854, vol. 8, page 1-12. Among other forms of rockers he describes one of a prismatic form, supported by its flat side on two pointed copper wires stretched in a vice (fig. 2).

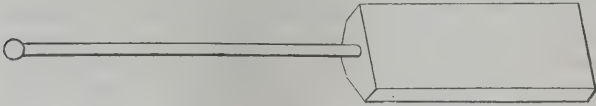

FIG. 3.

Tyndall also shows this form of rocker provided with a handle (fig. 3).

Seebeck's experiments are described and illustrated in Poggendorff's Annalen, vol. 51, page 1. The following are some of the forms of bearers and rockers used by him (fig. 4).

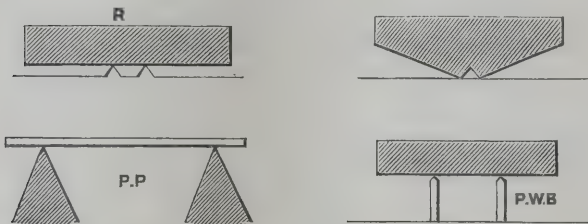

FIG. 4.

R, rocker; P, P, pyramidal points; P W, B, pointed wire bearer.

It will thus be readily seen what Rollman means when he speaks of "carbon bearer points stretched in a screw clamp and supporting a carbon rocker of prismatic form." Continuing Rollman's description of his instrument, he says "that the handle of the rocker rested upon a second suitable support, and to its end was soldered a wire which dipped into mercury, so that the current could easily be led through the carrier and rocker." As the source of electricity, he always used a single zinc-iron element. Frequently the vibrations obtained were slow, so that they could be easily counted; at other times they followed each other so rapidly as to run together into more or less high tones. The rapidity of the vibrations is chiefly due, as appears to me, to the distance of the bearer points, the weight, the shape, and the position of the centre of gravity of the rocker, and, finally, to the heating and expansion of the contact surfaces. No sparks appear at the two contact surfaces between the bearer and rocker, as the *contact is never broken there*. A slight spark is, of course, imperceptible to the eye, but its absence was ascertained by the polished brass rocker, which never showed the slightest trace of oxidation. The same thing was also proved by the galvanometer; when a portion of the current was by a branch wire led into the same, and the needle hardly went back, when the rocker, which had previously rested quiet, was lightly struck. The slight weakening of the current shown by the galvanometer is explained by the increase of resistance, because during vibration the rocker rests generally only upon one point and only rests momentarily upon both points when it falls upon the other side.

In view of the importance of this last paragraph, it disclosing the variable contact principle of the microphone, it is best to give it also in the original, viz.:—*Die durch diesen Rückgang (of galvanometer) angezeigte geringe Schwächung des Stromes erklärt sich aber durch die Vermehrung des Leitungswiderstandes da berin Tönen der Wieger meist auf einer*

Spitze schwebt und nur wenn er auf die andere Seite fällt momentan auf beiden Spitzen ruht.

Rollman in commenting upon Paalzow's statement concerning the operation of his instrument, says that if sparks were shown between the carrier and rocker, it must be attributed to the heavier current (Paalzow used 4 platinum elements), and, on the other hand, to the lighter piece of carbon, although it is not probable that *even in his case the contact was ever completely broken*.

It is not contended by the writer that the foregoing references disclose the principle of varying the strength of a battery current in unison with the rise and fall of vocal utterances or sound waves; but it is unquestionably true, that Rollman constructed an instrument for giving out sound, in which the variation of the electrical resistance was attained by two loose contacts of solid carbon under different degrees of contact pressure, effected by the passage of the current itself, and not by sound waves. In connection with the principle set forth by Rollman, that two loose carbon contacts will by change of position vary or modify the current in a closed electric circuit, it is well to refer to Stroh's experiments with carbon contacts in microphones, described in the London *Electrician* for April 28th, 1883. It is here stated that "it also appears evident that a current crossing a microphonic contact, has a strong tendency to cause vibratory disturbances, and it seems, therefore, reasonable to suppose that during microphonic action, even when all is in good adjustment, the sound waves which are transmitted are accompanied by other vibrations which are due to the passage of the current itself."

As the Trevelyan instruments of Paalzow and Rollman have a loose contact piece of carbon bearing lightly upon another contact piece of platinum or carbon and are to be used in a close galvanic circuit, it is self-evident from the close resemblance these instruments bear to microphones, that they can be used for telephonic transmission when combined with a proper receiving instrument.

The "half ring-shaped carbon contact" found in Paalzow's instrument, can be made to operate in the same manner as the carbon spheres and loose gravitating cylinders used in certain types of microphones or carbon transmitters, and the very instrument described and illustrated by Paalzow, will undoubtedly serve as a microphone transmitter, when used in connection with a battery current, not too powerful to cause sparking. As to Rollman's instrument, in which a carbon prism is supported upon carbon rods or bearers, it will be seen that it strongly resembles the instruments used by Professor Hughes in carrying out his experiments "on the action of sonorous vibrations in carrying the force of an electric current," first described in the *Proceedings of the Royal Society* for 1878, page 362.

Rollman's discovery can well be defined as the action of a vibrating solid carbon body for varying the force of an electric current in a closed circuit.

## THE INFLUENCE OF ELECTRIC RAILROADS UPON TRANSATLANTIC TELEGRAPHY.\*

By CHARLES CUTTRISS, Electrician Commercial Cable Company.

IT would hardly seem possible that the two above-mentioned industries could in any way clash, but the following account of trouble traced directly to an electric railroad will show that they do so, and that ultimately difficulties may arise which will have a serious effect upon transatlantic telegraphy, and unless some remedy is found, we may possibly have to resort to a less speedy communication between the two countries.

For many years it was the practice of cable companies to pick out some quiet, secluded spot in which to land their cables and to use land lines for the remain-

\* *Electrical Engineer*, New York.

ing distance to the nearest important city, using it as a radiating centre. This plan necessitated one transmission or repetition more than was actually necessary, and also caused a loss of time which it was very desirable to save. The Commercial Cable Company was the first to make an innovation, and in order to give quicker communication decided to land their sea cable at Coney Island, and continue it with an underground cable through Ocean Avenue and Brooklyn into the heart of this city, thereby practically making the terminus of their cable in Wall Street. Past experience had shown the advisability of using a return earth circuit as far as the sea, so the underground cable was constructed with four cores laid up in the usual manner and only separated from one another by about  $\frac{1}{32}$  of an inch.

The cable proper is connected to one of the cores by a permanent sea joint, and the diametrically opposite core, which is used as the return earth to the sea, is soldered directly to the sheathing wires of the sea cable, and the other two cores are kept spare in case of trouble.

This plan has given the utmost satisfaction until within the last few months, when we began to experience some trouble from occasional kicks on our receiving instrument; sometimes they would be so strong as to obliterate a signal. As these kicks are nothing unusual during the summer months, owing to thunderstorms and other atmospheric disturbances, they were for some weeks attributed to such causes.

During this period it was also noticed, when testing the cable, that the mirror seemed to be very unsteady, and had erratic movements, which denoted by their abruptness that the cause of disturbance was near this end of the cable, and was such as might be produced by a small fault.

To satisfy myself on this point I had the cores cut at the cable house on Coney Island, and while I was testing the undergrounds, the electrician at Canso, Nova Scotia (the distant end of the cable), was also testing the sea cable. The results showed that both the undergrounds and the cable were in perfect condition, but it was observed on the undergrounds that there was some disturbing cause in their neighbourhood; as, after perfectly discharging the cores, they would in a few seconds become quite heavily charged, always with the same potential; this phenomenon, of course, was only remarkable in the degree of charge. So far, we had arrived at only negative results, as the kicks, &c., were still present on joining up the working instrument.

About this time it came to my knowledge that there had recently been an electric railroad established, running from Prospect Park, Brooklyn, to Coney Island by way of the old Coney Island horse car road. Immediately it occurred to me that here possibly was the source of trouble. It must be remembered that ocean cables are operated by a recording instrument, that is so sensitive that a current of  $\frac{1}{1000}$ th of a milliampère will produce a distinct working signal; hence it is quite conceivable that, although the electric road does not in any part of its route approach our underground cables nearer than about *half a mile*, disturbances might be produced by the ever-varying power used in starting and running the cars. To prove the correctness of the assumption, I connected a telephone between the cable and its return earth and could distinctly hear the starting and stopping of the cars. The telephone was then connected to the cable and a local earth in the city, namely, the water pipes; the sounds then became so much louder that they could be heard with the telephone a short distance from the car. The testing galvanometer, a Thomson astatic, of course could not pick up such rapid vibrations, but it shows deflections and kicks to such a degree that we have sometimes been obliged to give up testing and try at a more favourable time, such as 1 or 2 a.m., when the cars have stopped for the night. This naturally is somewhat inconvenient.

Now comes the question, if the disturbance is so severe with the railroad at a distance of half a mile or 2,640 feet, what would be the effect on the company's

property if at some time an electric road should be projected down Ocean Avenue where the rails would in all probability be within 4 or 5 feet of the cable for a minimum distance of  $5\frac{1}{2}$  miles? With telephones and ordinary telegraph instruments the use of a metallic circuit is a good protection, but in the present case it is proved that a metallic circuit through the disturbed district does not grant immunity from serious disturbance.

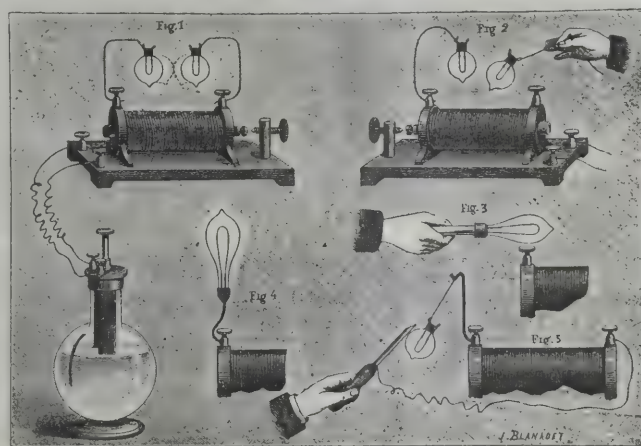

One point is still to be determined in regard to this phenomenon, namely, to ascertain for a certainty whether the effects produced are to be attributed to conduction through the earth and water to our armouring, or if it is an inductive effect. The fact, nevertheless, remains that if electric roads should be greatly augmented in our immediate vicinity the disturbances on our lines will be seriously increased, and at present it is difficult to conceive of any remedy other than the adoption by the roads of a double trolley system.

The tests show our undergrounds to have a dielectric resistance of about 350 megohms per mile, so the idea of any leakage cannot be entertained.

### EXPERIMENTS WITH ELECTRICITY.

WE, says *La Nature*, have received from a subscriber in Mexico a highly interesting description of some experiments with the Rhumkorff coil and incandescent lamps. These have been repeated by us at the laboratory attached to the Halles electric station, and we are now in a position to lay them before our readers, together with some hints of a practical nature.

By attaching two curved wires, each supporting an incandescent lamp, to the terminals of the secondary circuit of a Rhumkorff coil (fig. 1), we observe an approximation of the two lamps at the moment of the current's passing. The phenomena is particularly marked at a distance between the lamps of 3 to 5

millimetres. Care must be taken that the supports shall be very flexible, and for this purpose a copper wire, 1 millimetre in diameter, and insulated with gutta-percha, will be found perfectly suitable. It is likewise important to avoid direct sparks between the lamp sockets. It is necessary to the attraction that there should be a discharge traversing the lamps and compelling the approximation. By suspending one of the lamps (fig. 2) and holding the other in the hand, the attraction between them will be the same. A lamp placed upon a terminal of the secondary circuit of a Rhumkorff coil (fig. 3) will become luminous, and it will be only necessary to approximate a lamp to a terminal to obtain gleams of equal brilliancy (fig. 4); suspend a lamp by a flexible wire at one terminal (fig. 5) and approximate to it any point in connection with the other terminal, and an attracted and sustained gleam will be observable. These experiments may be varied at will; those above-described are intended as examples merely.

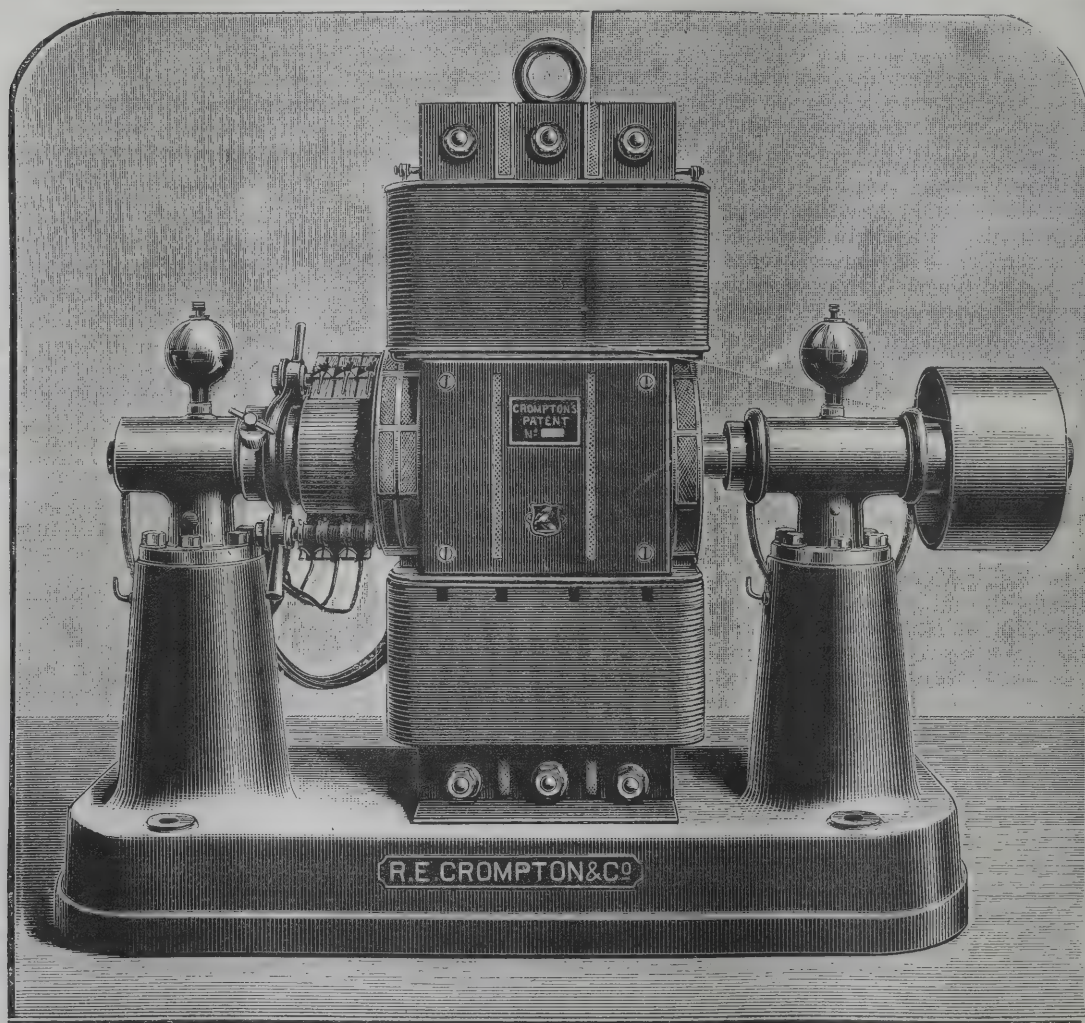

**THE SOUTHEND PIER ELECTRIC TRAMWAY.**

ELECTRICAL traction in this country is making slow but sure progress. Although engineers on this side have been confined to the development of underground systems of conductors, or to the use of accumulators, in neither of the latter two cases has sufficient success been hitherto attained in England to sufficiently attract the public attention to the manifold advantages which any system of electrical haulage presents.

It is therefore with pleasure that we notice an extremely successful addition to the few electrical tramways now being worked in this country, and to the opening of which we have already briefly alluded. The Southend Local Board, which is a very enterprising public body, and has introduced a large number of local improvements with a view of further popularising the

and build the car, motor, &c. By good management and a willing staff, they were fortunate enough to succeed in carrying out their contract one day within the time, and extreme credit is due to everyone concerned, particularly to Mr. Chamen, the chief of their outdoor staff, and to Mr. Scott Moncrieff, who is resident at Southend, for the extraordinary rapidity with which the work has been carried out, without a hitch or alteration in the original design.

The generating plant consists of a horizontal compound engine by Davey Paxman, supplied with steam by a boiler of locomotive type. Both are extremely favourable examples of the highly economical and extremely efficient class of steam engine that this well-known firm is now turning out. This engine drives a Crompton compound dynamo of their standard type, having an output of 150 ampères by 200 volts at the terminals, and having a commercial efficiency exceed-

CROMPTON DYNAMO FOR GENERATING CURRENT.

already rapidly increasing town of Southend, has recently constructed a new iron pier, costing about £80,000, to replace the old wooden one, which was itself one of the most remarkable constructions of the kind in the country, being a mile and a quarter long, and fitted with a horse tramway. The board decided to replace horse traction on the new pier by an electric tramway, and after specifications had been issued, Messrs. Crompton secured the contract in public competition. One feature of this contract was the short period in which it had to be carried out, namely, that a length of three-quarters of a mile, with an electrical tramcar, and all the plant, as well as the lighting of the pier, should be completely set to work on the day previous to the August bank holiday, in order that the traffic might be secured for the new tramway.

This only gave the contractors six weeks in which to lay the track and supply all the generating machinery

ing 90 per cent. The electrical energy is conducted from the engine room by insulated cables carried along the pier to the commencement of the car track, and from thence to the end of the pier. Messrs. Crompton determined to use their stock pattern flat strip copper conductor that they have been using for the past four years in the streets of London, the whole of the supports, insulators, and straining gear being taken from the stock, and identical in all respects with those they have used in upwards of 30 miles of streets in Belgravia, Kensington, and Notting Hill. The strip used in this instance is an inch wide by .134 inch thick, and is supported at intervals of 15 yards by vertical insulators, and strained in lengths of 85 yards by straining gear having volute springs, to compensate for expansion due to differences of temperature, the insulators in both cases being the stock pattern used for street mains.

The track consists of a pair of Vignoles rails 3-inch

by 6-inch gauge, the strip conductor being laid about one foot distant from one of the rails, and one inch below the level of the rail tops. The rails themselves are used for the return. The car was built for Messrs. Crompton's order by Messrs. Kerr Stuart, and the motor is a stock pattern Crompton dynamo, the speed being reduced 3 to 1 by simple spur gearing. The motor is fixed below the bottom of the car, and access can be given to it either by bringing the car over the pit or by lifting a trap in the flooring. The car is driven from either end, and the means of regulation are extremely simple. A pair of handles, one for reversing and one for starting, with the ordinary brake wheel in front of the driver, being all that is required.

The maximum speed of the car is 20 miles an hour, but in ordinary running the speed is kept down to about 12 to 14 miles an hour, so that the journey along the pier, which used to occupy previously about 15 minutes, is now performed in three to four minutes. The contact apparatus for taking the current through the strip consists of rubbing shoes, especially designed for this purpose by Mr. Chamen, and which appears to act very well, and without apparently causing any wear to the surface of the copper strip.

An official trial was made by Dr. Hopkinson, consulting engineer to the Local Board, on the 30th of July. He expressed himself completely satisfied with the workman-like manner and extreme celerity in which

## PARLIAMENTARY NOTES.

### TELEGRAPH CLERKS.

IN the House of Commons last Friday night, in answer to Mr. MacNeill,

Sir H. MAXWELL said: Mr. Quin, lately employed as a telegraph clerk at the central office, was dismissed for using the telegraph wire for private purposes, to the hindrance of public messages. Neither was the object with which he used the wires calculated to bespeak a lenient view of his conduct. Having formed one of a deputation to his controller, which pledged itself to a particular line of action, he had no sooner left the room than he proceeded to the telegraph wires and advocated another. Thus persons at a distance were stirred up by him to adopt the very course which the deputation, of which he was a member, had just assured the Department would not be adopted. For this act of duplicity, added to his infraction of a rule to which the Department attaches the highest importance, that the public wires shall not be used for private purposes, there was, in the Postmaster-General's judgment, only one suitable punishment, and that was dismissal. Mr. Quin's conduct inside the office had hitherto been good. There are many instances of clerks and others being dismissed for a first offence.

CAR.

END VIEW OF CAR  $\frac{1}{2}$  MILE UP PIER.

the work had been carried out, and the members of the Local Board, and the townspeople generally, have over and over again expressed their extreme satisfaction with the unexpectedly rapid completion of the work, and its great success. The day following the official trial the car was handed over to the Local Board for regular running, and has been running ever since without breakage or interruption of any kind. On Bank Holiday the car was overloaded every journey, and the takings amounted to upwards of £40, and ever since that day the takings have been heavy.

It is evident from this that the Southend authorities have made a good investment of the local funds in introducing this electrical tramway. The horsepower absorbed in driving a loaded car at full speed appears to be considerably below what Messrs. Crompton estimated it would be.

As soon as the pressure of public traffic of this season is over, Messrs. Crompton hope to be able to make a set of experiments to show what is the real tractive force required on this class of electrical railway, and intend to make these results public.

**The Electric Light in Paris.**—The right side of the Rue Auber, from the Rue Scribe to the Boulevard Haussmann, is now lighted by electricity. The arc lamps have been placed in the old gas lamps in the same way as at the Palais Royal.

### LIGHTING OF THE NATURAL HISTORY MUSEUM.

On the report of the votes passed in Committee of Supply,

Sir G. CAMPBELL, on the vote for the British Museum, asked whether arrangements could not be made for the lighting of the Natural History Museum, so that it could be used in the evening.

Mr. JACKSON said that, as the introduction of the electric light was a matter of experiment, it had been thought advisable to begin with the British Museum, because it was nearer to the masses of the people, and was more easily reached by them than was the Natural History Museum. The same pressure had not as yet been put upon the trustees to light the Natural History Museum, but experiments would be made with a view to the illumination of the building, should it ultimately be determined upon.

### SUBSIDIES TO TELEGRAPH COMPANIES.

On the report of the vote for subsidies to telegraph companies,

Dr. CAMERON moved the reduction of the vote by £6,075, being the amount of the subsidy to the Halifax and Bermuda Telegraph Company. He remarked that the circumstances attending the laying of this cable bore a most suspicious resemblance to an unbusiness-like job. The telegraph line from Halifax to Bermuda was one chiefly of strategic importance. In 1886

tenders were invited, and the lowest was that of the International Cable Company, which offered to do the work for a subsidy of £8,000 a year for 20 years. That was considered excessive, and in 1888 fresh tenders were invited and three were sent in, the same company being again lowest, with an offer to do it for a subsidy of £6,923 a year for 20 years. That offer was accepted, but subsequently the company was allowed to withdraw it on account of a rise in the material, presumably owing to the corner in copper. Tenders were again invited, and the International Cable Company was again the lowest, and was accepted at a subsidy of £8,100 for 20 years, but before the contract had been ratified the price of copper had collapsed, and, in addition, it must be remembered that a lower tender had been refused in 1886, on the ground that it was excessive. Again, the condition that £100,000 should be subscribed and fully paid up had not been insisted upon, although it was in the Treasury minute.

The Halifax and Bermuda Telegraph Company had its articles of association subscribed by one merchant, one accountant, one agent, and four clerks. The nominal capital amounted to £50,000, but according to information which came to Somerset House, only £35 had been subscribed by the gentlemen named in the articles. He would like to ask the right hon. gentleman what amount of subscribed capital this company had. The prospectus of the company involved statements which might probably prove to be extremely misleading about a subsidy from Her Majesty's Government. In his opinion, the Government ought to have warned the public against the statements contained in the prospectus. The company having been inaugurated, was, to a certain extent, connected with Her Majesty's Government, and they were responsible for it, because, under the contract, they nominated one member of the board, and consequently had a right to all the information about the company. He asked the secretary to the Treasury to state what was the amount of capital subscribed to this company on the 12th of April; what was the date on which he agreed formally to transfer the contract to them, and what amount of capital was subscribed at that date, independently of the debentures on which they got the country to subscribe money on grossly false pretences. He had brought this matter forward for two reasons. In the first place, it involved a gross infraction of the control of that House over contracts submitted to it for ratification; secondly, because of the peculiarities of the whole transaction from beginning to end.

Mr. JACKSON observed that he had already given a full explanation of the facts of the case, and went on to say that many questions had been asked which he was, of course, unable to answer. He must decline altogether, on the part of the Government, to accept responsibility for any statements which might be published in a prospectus. The whole question lay in a nutshell. The Government had taken a new departure with the object of securing the laying of the cable. The security was provided, the capital was subscribed, and the cable was to-day in working order. He thought the Treasury were to be congratulated on the economical manner in which they had carried out the undertaking.

Dr. CAMERON insisted upon a division, when 37 voted for the reduction of the vote and 23 against it.

The vote was then agreed to.

#### TELEGRAPHISTS.

In the House of Commons on Saturday, in answer to Mr. P. O'Brien, Sir H. MAXWELL said:—The scale introduced on July 11th last fixed the wages of second-class telegraphists at 12s. a week for the first year, at 14s. a week for the second year, and 18s. a week for the third year, thereafter rising by 2s. annually to 40s. a week. This scale is on the whole better, far better, than the one it superseded. In connection with the old scale, however, there was an arrangement under which a learner, if fully qualified, could receive 16s. on appointment, and it is being considered whether a similar advantage should not be given to those learners whose

employment began before the new scale was introduced.

#### TELEGRAPH RATES TO AUSTRALIA.

Mr. HENNIKER HEATON asked the Chancellor of the Exchequer whether he was aware that the Australian Governments had contributed a sum of £32,000 a year for the past eleven years to the Eastern Telegraph Company for maintaining and cheapening telegraph communication between Australia and Europe; whether the British Government contributed any portion of the subsidy; whether an application was made this year by the Agents-General of the New South Wales, the Victorian, and the South Australian Governments to the British Government to join in a guarantee against loss, on condition that the telegraph companies reduced the rates to and from Australia from 9s. 4d. to 4s. per word for ordinary messages, and from 7s. 5d. to 2s. 6d. per word for Government messages, and what answer, if any, was given to the Australian Governments.

THE CHANCELLOR OF THE EXCHEQUER: I understand that the subsidy in question was granted mainly with a view to the duplication of the cables between Java and Australia. The British Government did not contribute to the subsidy. An application to the effect indicated in the third paragraph of the hon. member's question was made, but Her Majesty's Government was unable to accede to it.

#### NEW PATENTS—1890.

12171. "Improvements in electric motor mechanism." S. E. MOWER. Dated August 5. (Complete.)
- 12221 "An improved apparatus for the measurement of electrical energy." H. H. LAKE. (Communicated by E. Weston, United States.) Dated August 5. (Complete.)
12228. "Improvements in commutators for dynamo-electric machines." J. W. EASTON. Dated August 5. (Complete.)
12231. "Commutators for electrical machines." W. W. VAIL. Dated August 5. (Complete.)
12244. "Improvements in sockets for electric lamps." A. V. NEWTON. (Communicated by A. Swan, United States.) Dated August 5.
12247. "Improvements in and relating to electric lamps or lighting apparatus." H. H. LAKE. (Communicated by G. C. Pyle, United States.) Dated August 5. (Complete.)
12337. "The indestructible electric filament used for incandescent electric light." C. HERZOG. Dated August 7.
12352. "Making electric contacts for ringing electric bells, and other purposes." A. H. BAGNOLD. Dated August 7.
12394. "Composition brushes for electric lighting." W. P. ODLUM. Dated August 8.
12422. "An electric pendulum for firing ships' guns." J. JENG. Dated August 8. (Complete.)
12439. "Improvements in and relating to electric lamps or lighting apparatus." A. L. SHEPARD. Dated August 8.
12440. "Portable combination electrical testing set." A. A. DAY and H. J. DOWSING. Dated August 8.
12504. "Improvements in holders for incandescent electric lamps." E. P. ALLAM. Dated August 9.

#### ABSTRACTS

#### OF PUBLISHED SPECIFICATIONS, 1889.

6458. "Method of regulating the electric current produced by electric generators driven by a motor having an irregular or variable speed." P. HOHO. Dated April 15. 1s. 1d. The object of the invention is to produce a current of a pre-determined strength, either constant or variable in a predetermined manner, in an electric machine, the speed of which varies within certain limits, by operating on the intensity of the field magnets. 5 claims.

9258. "Improvements in electric signal lamps and appliances connected therewith." F. L. RAWSON and W. S. RAWSON. Dated June 4. 8d. Surrounding the lamp are a number of blinds or shutters which may revolve on vertical pins and be actuated by a wheel or similar mechanism which by its motion engages with each shutter, and causes them to turn through about 90°. The motion of this wheel can be produced by the movement of an armature, due to the magnetic attraction of an electro-magnet. The passage of a current through the electro-magnet causes the armature to move and carry with it the wheel against the force of a coiled spring. By this action the shutters may be opened or shut. On the cessation of the current the spring carries the wheel back to its original position, and the shutters are shut or

opened by the wheel. By opening and closing the shutters flashes of light are seen round in all directions, and so can be used for signalling purposes. 6 claims.

10695. "Improvements in electric batteries." H. H. LAKE. (Communicated from abroad by C. A. Hussey and E. H. Brown, both of New York.) Dated July 2. 8d. Consists in the combination in a battery of a porous diaphragm for separating the two fluids, and extending solely in a horizontal or approximately horizontal plane. 4 claims.

10696. "Improvements in electric batteries." H. H. LAKE. (Communicated from abroad by C. A. Hussey and E. H. Brown, both of New York.) Dated July 2. 8d. Consists in the combination in a battery with a cell and negative and positive elements of a porous diaphragm arranged in the upper part of the cell below the positive element, and a piece of metal which is located below the porous diaphragm, and is of such character that it will decompose the salt of copper solution. 3 claims.

10878. "Improvements relating to electric telephones." D. B. MORISON. Dated July 5. 11d. The receiver and transmitter are mounted upon the extremities of a bent rod or of a bent tube through which are passed the conductors for one or the other of the said instruments, a part of the said rod or tube forming a handle, or being provided with a suitable handle of porcelain, wood or other suitable material. The conductors for both the transmitter and the receiver preferably extend through the casing of one or the other of the said instruments, and are connected with terminals attached to a suitable base or stand. The said tube is sometimes made telescopic or otherwise adjustable so that the relative positions of the two instruments can be varied. Another feature of the invention is the provision of a support for the said transmitter and receiver, which is so constructed and arranged that the weight of the combined instruments, when placed on the said support, will cause the interruption of the telephone circuit and switch in the signal or call-bell, suitable provision being made for automatically interrupting the signal or call-bell circuit and switching in the telephonic instruments when the latter are removed from the said support. 4 claims.

10940. "Improvements in electrical couplings used in electrically lighting railway trains, and for other purposes." F. T. HOLLINS. Dated July 8. 8d. The object of this invention, whilst still leaving this contact-piece or circuit closing device, perfectly automatic in its action when the couplings are taken apart, under ordinary circumstances is to provide that when the electric half-coupling at the slipping end of a slip coach is pulled apart from any other half coupling it shall, in coming apart, leave the contact-piece in the half coupling attached to the main portion of the train out of contact with the lamp circuit or lamp and battery circuit. 4 claims.

11179. "An electric meter." SIEMENS BROTHERS AND COMPANY. (Communicated from abroad by the firm of Siemens and Halske, of Berlin.) Dated July 11. 8d. This invention relates to an electric meter, wherein a counter registers the number of oscillations of a bar of soft iron subject to the influence of the electrical current to be measured or of a known fraction thereof. 3 claims.

11191. "Improvements in roses for supporting electric lamps." W. A. S. BENSON. Dated July 11. 6d. The inventor connects the projecting ends of the leads in the wall or ceiling to contact makers, carried by a rosette of wood or other material fixed to the wall, like the rosette used for a gas bracket. The ends of the wires of the fittings are attached to spring contact makers, which are carried by a disc or cone similar to that used for gas brackets and called the "back." It is furnished with screw holes, so that it can be attached by screws to the rosette, as is done in fixing a gas bracket. 3 claims.

11528. "Improvements in electrode plates for electric accumulators." C. BEYER and G. HAGEN. Dated July 19. 8d. Relates to electrodes formed of a skeleton, which serves for the reception of the filling or active material, and which comprises two plates constructed in the form of openwork frames, nets, or gratings, that are connected by numerous cross-pieces, and are surrounded by a solid frame or border. 2 claims.

12444. "Improvements in switchboards for telephone systems." J. R. SMITH. Dated August 6. 8d. The object of the invention is to provide a switchboard specially adapted for telephone systems, which will enable any subscriber to make a direct connection with any other subscriber in the system without the intervention of a third party at a central office. 7 claims.

## CORRESPONDENCE.

### Cable Testing.

My attention has been drawn to a paragraph in the *ELECTRICAL REVIEW* for the 18th ult., to which absence from England has prevented me from replying earlier.

The paragraph in question is intended as a criticism on an article on cable-testing, which I published in

*The Electrician* for the 11th ult., and is of so weak and puerile a nature, that I should have refrained from commenting upon it, had I not felt that my silence, instead of being attributed to contempt for such unscientific criticism, might possibly, by some persons, have been construed into inability to reply to the attack.

I cannot boast myself a regular reader of the *ELECTRICAL REVIEW*, but, if I ever chance to take up a copy of this paper, I am always reminded of the tale of the Staffordshire miners, who are reported to greet the appearance of a stranger by "'eaving 'arf a brick at 'is 'ed." Whenever anything is done in connection with electrical engineering which is beyond the somewhat limited experience of the editors of the *ELECTRICAL REVIEW*, they do not fail to 'eave the 'arf brick at the 'ed of the electrical stranger, although in their hands it is neither so efficient nor so weighty a weapon as in the hands of the Staffordshire miner; and, instead of annihilating the "stranger," not infrequently recoils on the assailant.

But I must remind the writer, or writers, of the paragraph to which I am referring, that assertion is not argument, nor inaccurate statement, proof. If the method which I have described be so ancient a one it is a somewhat curious fact that it is not described in any of the numerous text-books devoted to cable testing, and it is a still more curious fact that telegraph engineers of large experience and considerable knowledge of cable testing should be admittedly ignorant of this "so simply obvious" (*sic*) a method.

I therefore challenge the *ELECTRICAL REVIEW* to justify the gaseous effusion which appeared in their publication for July 18th, by giving chapter and verse for their statements, that the method described is neither novel nor interesting, or to acknowledge that they now, as so frequently before, have written at random.

H. Cuthbert Hall.

In response to our request that independent testimony to the correctness of our statement should be given, we have received the following communications from a number of gentlemen to whom we tender our cordial thanks.—EDS. *ELEC. REV.* :—

Mr. E. MARCH WEBB, electrician-in-chief to the India Rubber and Gutta Percha Company, Silvertown, says :—

"The system is as old as described. The particular method of application may vary according to individual idea. It is well known, in one shape or another, to every electrician."

To Mr. Webb's communication we append another from a gentleman with whose text-book Mr. Hall may possibly be acquainted :—

"It is evident that Mr. Cuthbert Hall can have had no experience whatever of cable factories, or he would not have made such an exceedingly absurd claim of originality for the method of localising faults in insulated wires which he describes. There is not a cable factory in existence, I believe, where the method described, and modifications of it, have not been, at some period or other, in almost daily use; this I can testify as the result of 20 years' experience. It may be that the method is not specifically described in any text book, but the reason of this is that it is so obvious as not to require description. I may add that the method is in daily operation at the Gloucester Road factory of the Postal Telegraph Department, and has been so ever since insulated wire has been in use. Mr. Hall's remarks relative to the Editors' limited experience is amusing, seeing that these gentlemen have, with the exception of one firm, probably had a longer and wider experience in the testing of insulated wire for submarine cables and other purposes than anyone in the electrical profession.

"H. R. KEMPE.

"Electricians' Department, General Post Office."

Messrs. WALTER T. GLOVER & Co.'s Electrician informs us that the method of fault testing with revolving drums, described by Mr. H. Cuthbert Hall,

has been practised in their works for the past five years.

The MANAGER OF HENLEY'S TELEGRAPH WORKS sends us the following:—Referring to yours of 15th inst. The system mentioned was used by us over 20 years ago, but has been abandoned in favour of a more practical method.

My attention having been called to Mr. Cuthbert Hall's system of testing, and also to a communication from him in reference to it, I would state that the method devised by him, which I have no doubt he thought was original at the time he invented it, is at the least forty years old. The germs, and a good deal more than the germs of this method of testing, were introduced by my brother, the late C. F. Varley, to test defectively insulated wires in railway tunnels, shortly after gutta-percha covered wires replaced suspended ones for tunnel work. The faults were localised in the following way: one end of the gutta-percha covered wire was connected to one pole of, say, 300 cells of a sand battery, the other pole being earthed, a piece of flannel soaked in acid and water was wrapped round the gutta-percha wire and embraced by the fingers of a lineman who walked through the tunnel, passing the flannel tube over the outside of the gutta-percha covering; when the fault was reached, the lineman's fingers and body acted the part of a galvanometer, the current passing through him to the earth and the position of the fault was afterwards more exactly localised by an ordinary lineman's detector.

When gutta-percha insulated wires came into use for underground circuits, the Varley system of testing was further developed by its introducer at the Gloucester Road Telegraph Stores. The coils of insulated wire were wrapped on a drum in a *precisely* similar manner to that described by Mr. Hall, and passed through an insulated trough containing acid and water.

The battery employed was a carefully insulated sulphate battery of seven or eight hundred volts, the troughs being suspended by gutta-percha bands from the roof of the workshop. One pole of the battery was in electrical connection with the copper core of the gutta-percha coated wire, and the other battery pole was connected to one of the two terminals of a very sensitive horizontal astatic galvanometer, made by the late Mr. Henley, and which stood on a strong oak bench, resting on a solid brick foundation, the second terminal of the galvanometer was electrically connected with the trough containing the acidulated water through which the coated wire passed, by being wound on to a second drum.

I shall be well within the mark, I think, if I say hundreds of miles of wire were tested in the manner described, under the direction of the late Mr. Muirhead, who was out-door superintendent of the old Telegraph Company, and who had charge of the workshops and the Store Department at Gloucester Road. I should think it probable that Dr. Alexander Muirhead may remember seeing this system of testing in practical use when he was a schoolboy, seeing that his father lived on the company's premises, at all events, Latimer Clark will be very familiar with the system of testing introduced by my late brother.

I may mention that the late Dr. Wildman Whitehouse reinvented the Varley system, and finding he had been anticipated, he called upon my brother. I was present at the interview, which took place in 1859 or 1860.

Mr. Cuthbert Hall would really appear to labour under the hallucination that the stock in trade of the editorial department of the ELECTRICAL REVIEW includes, among other things, a plentiful supply of "arf bricks"; possibly *his* experience in electrical engineering is "somewhat limited," for were he better posted up, he would be very likely to know that the experience of the editors of the ELECTRICAL REVIEW in matters of testing, more especially in connection with submarine cables, is considerable. If he were to read

the ELECTRICAL REVIEW regularly, instead of taking it up *only* occasionally, he might possibly become more charitably minded, and be less disposed than he would now seem to be, to take a leaf out of the book of our very good friends, the Staffordshire miners, and "leave arf bricks at the 'eds" of the editors.

S. A. Varley.

Another correspondent writes:—"I have gone through Hall's paper in the *Electrician*, and also your leaderette, and I cannot see anything to alter in your remarks. The only fresh point I notice in Hall's paper is the fact that he cuts an aperture in the centre of the drum to admit the end. Now, no one but a tyro would do that. All cable drums and insulated core drums now-a-days have a hole cut at the side or end of the drum, so as to allow of the end, and as much more as may be required to be outside for testing, &c.

"Such a simple matter of testing is not usually described in text books, nor are methods of connecting up, &c.; the original method of fault-finding by passing through an insulated water trough will be found in Culley, and was known to everyone.

"In Kempe's last edition, describing Jacob's method (which, by the way, Hall does not seem to know), p. 438, testing for faults from core and using *two drums* is referred to. The test only is explained, and the simple connections required with a revolving drum are naturally not referred to or explained, they are 'simply obvious' to the meanest understanding. Moving contacts may vary according to one's ideas, but the method of testing described by Hall is ancient.

"I am told that testing has been carried out at Helsby and at Henley's, and also Siemens', with revolving drums. This must be so, especially with Jacob's test. When swift's are used, then connection is made either with a brush on the spindle, or the end is attached to a suspended connector working in a swivel.

"The insulated trough, with metal plate, I have used for this purpose in the long past, and in the present, it has been of the form adopted for testing joints by Clark's method of accumulation. This I found handy for both purposes, and my present one is built on same lines; but I added a slight improvement to my trough (which was insulated at the four corners by telephone knob insulators screwed in). I found my trough (2 feet about) rather short, for minute faults went through sometimes before the water got at them. I accordingly mounted in the centre of the trough a small drum, with a circumference of about 3 feet; two turns round this, and the trough gave me a practical length of 8 to 9 feet, with satisfactory results.

"It is very difficult to give any dates or particulars as to the use of this simple means of fault testing, but the method of testing G.P. wire through water in an insulated trough was employed when I was a boy. The use of a revolving drum *only* introduced a friction contact instead of a fixed one, the method of testing being the same."

#### Fall of Potential.

"Works Manager" may possibly prefer a rule which avoids reference to a table of resistances and the calculations often needed, and enables him to make use of the 1,000 ampères square inch table he already has. In similar cables the fall of potential varies directly as the length in yards (to and fro) multiplied by the current. In the example given,  $200 \times 10 : 75 \times 15 :: 2.2 : 1.2375$ . Stated as an equation fall of potential,  $e c$

$$= \frac{2.2 \times 75 \times 15}{200 \times 10} = 1.2375, \text{ i.e., a current of 15 ampères}$$

in a 7/16 copper circuit 75 yards long causes a fall of potential of 1.2375 volts. The result given last week is, by a slip, 1.275 instead of 1.2375: and the resistance of 75 yards 7/16 is given as .085 instead of .0825 ohm.

A. Whalley.

DELIVERY OF TELEGRAMS.

ANOTHER storm has been raised about the management of the Post Office. No sooner is the vexatious business of the telegraph clerks disposed of, than the attention of the public is brought to bear on the internal working of the telegraph department in regard to the delivery of telegrams.

Prof. George Darwin, towards the end of last week, sent a complaint to the *Times* as to the non-delivery of a telegram. The grievance, in the Professor's own words, is: "A friend recently telegraphed to me from America, addressing the message, 'Darwin, Cambridge,' and it was not delivered on account of insufficient address. He repeated the attempt three times, and I learn from the General Post Office that there are others of my name residing in Cambridge, and that it was impossible to know with certainty for whom the message was intended. The other persons are my brothers. The non-delivery of the message was the occasion of the unnecessary sailing of a friend to America."

There can be little doubt that the Professor's allegation is not altogether well founded, and that the fault lay with his American friend; but while regretting the circumstance, one might have placed it to the credit of unaccountable accidents from which human beings possess no immunity, had it not been followed by a long series of like complaints. The Professor, as it were, had applied the match, and the explosion resulted in due course. This opening of the subject has given the opportunity for many to air their opinions as to desirable alterations.

Lord Sackville Cecil, in his letter, draws attention to other points besides transmission, which require speedy attention. It is known that telegrams handed in late in the evening at many offices are sometimes kept over until next morning. This is considered by some to be a gross breach of contract on the part of the postal authorities, but people who show

a desire to ventilate supposed grievances speak, in most cases, without any knowledge of the regulations affecting the transmission of telegrams. No one thinks of using the telegraph wires except in urgent cases, and if a letter would reach its destination in the same time as a telegram, it is asked, where is its use? It is, of course, incumbent on the office to see that a message is delivered as quickly as possible, or the official should state frankly to customers that he will not undertake to deliver them the same evening. This course is, we believe, generally pursued, although there may be instances in which the telegraph clerk is as ignorant of the regulations as the sender of the message. It is clearly incumbent upon the public to know in what the contract which is said to be broken really consists, otherwise it is sheer folly to fill the columns of the daily papers with complaints which have no existence in fact.

MANUAL TRAINING.

IN a recent issue of the American journal, "*Bradstreet's*," a description is given of the School of Manual Training at Baltimore. This institution claims to be the pioneer public manual training school, as well as the only absolutely free school of the sort in the world. The school was opened in 1884 with 60 pupils and 4 teachers; the scholars now number 549, with 15 instructors. The principal object of the training is the teaching of manual work, the literary instruction, which forms the chief motive of ordinary schools, being here but a department. The teaching of trades is not so much a desideratum as education in the use of tools and the early stages of mechanical industries.

The regular course extends over three years, but a shorter course of two years is suited to those who are unable to go through the longer training.

The daily work comprises instruction in the shops, draught-rooms, physical laboratory, and literary classes. During the first year of training, 15 weeks are devoted

to carpentry, 5 to wood-turning, and 20 to forging. In the second year, 15 weeks are given to pattern making, 5 to moulding, 15 to vice work, and 5 to soldering and brazing. Instruction is given as to the use and care of tools, designing work, and the nature of the materials employed.

Each class makes some special design for graduation, and this year a 10 horse-power dynamo, 13 lathes, and a Gordon printing press, have been undertaken.

The dynamo will be set up, and is expected to furnish a sufficient supply of electrical energy for the lighting of the buildings with incandescence lamps. The students also do all the plating required, and carry out all repairs to the machinery in use in the establishment.

There can be little doubt as to the value of schools of this nature, providing as they do practical instruction, and affording a means by which youngsters, who in after life must depend upon manual work, can readily give their attention to, and be guided in the study of, their individual bent. It would certainly appear desirable that in the higher classes of our Board Schools some attempt in this direction should be made.

#### Utilisation of Water Power.

IT would seem that the scheme for the utilisation of the Niagara Falls for the purpose of distributing power to a number of factories at Buffalo, has assumed a definite shape. A piece of land some distance above the Falls has been acquired, and a very strong syndicate has taken the work in hand. It is stated that 4 per cent. of the river flow will provide 120,000 horse-power, supposing that a fall of 140 feet is adopted. A lateral canal will carry the water required from the main river to vertical shafts, in which turbines, said to be the largest yet designed, will be placed. The town of Buffalo is 18 miles distant from the Falls, and it is as yet undecided as to the method to be employed in transmitting the power. The choice is not a large one, lying between rope transmission, as at Schaffhausen, compressed air, as at Paris and Birmingham, water pressure, as in London, and electricity. The Cataract Company has invited tenders, and the plans will be submitted to a scientific international committee. Meanwhile, a scheme of considerable magnitude is actually in course of execution at Helena, Montana, where the Missouri Power Company is building an immense dam across the Missouri River for the purpose of utilising the water power. The dam is a timber structure, 800 feet long and 47 feet high, and the reservoir thus formed will cover an area of about 429 square miles. The water will be carried through a tunnel to the turbines, and it is expected that 20,000 horse-power will be generated, the power being then transmitted electrically to the various mills.

#### How to Advertise.

A REMARKABLE supplement has been issued by our Italian contemporary, *L'Elettricità*. It consists of 24 quarto pages of illustrated matter referring solely to the Thomson-Houston International Company and to their exhibits shown at the Paris Exhibition. There are described the Thomson-Houston dynamo, three wire system of distribution, method of traction, alternate current dynamo, arc and glow lamps, electric welding, &c. In

the list referring to the lighting of Europe, the number of towns in which the system is in operation is given as 64, and several installations are to be found in some of these. The arc lamps in use in Europe comprise 3,836 and the incandescent lamps 17,055. Particulars are also given of the extensive use of the system of lighting and traction in America, and of which we gave details some time ago. The number, which, by the way, has only this week been issued as a supplement to one published a fortnight ago, winds up with testimonials, and is unique in the annals of technical advertising.

#### Cataphoric Medication.

IN the early autumn of last year Dr. Harries and Mr. H. Newman Lawrence made conclusive experiments on this subject and have since carried out this treatment, to which Dr. Harries gave the name of "Cataphoric Medication," in their regular practice at the Institute of Medical Electricity. In Mr. Lawrence's address to the City and Guilds' Old Students Association, published in the REVIEW of December 27th, 1889, he spoke of this treatment as in actual practice, and it is again mentioned in a note on the 8th of this month. Dr. Harries has referred, in his letter to us, to other dates in which he made the matter public.

#### Cable Testing.

THE letter which we publish from Mr. Cuthbert Hall does not show him in any better light than did his first communication; it was perhaps too much to expect the *amende honorable* from a gentleman whose character is so clearly defined by his writings. His reference to the Marchant engine, and other allusions, show him to be better acquainted with the REVIEW than he at first gave himself credit for; he might have gone further and acknowledged us as being the means of exposing that matter and bringing its career to a prompt and crushing end, but he evidently prefers dealing with half truths, probably under the impression that many of our subscribers may not be acquainted with the circumstances under which this incident took place. It will be noticed that all reference to Glover's and Henley's Works is carefully avoided, and as for the remainder of his remarks, we leave them to the tender mercies of such of our readers as may care to carry the matter further; or to the journal which first gave our correspondent publicity.

#### Kemmler's Execution.

THE *Scientific American*, of all the transatlantic papers to hand, seems to have taken the fairest and most impartial view of Kemmler's execution. After stating that the apparatus employed was sure and effective and that the criminal was instantly killed, our contemporary argues as follows:—"The most intelligent of the witnesses, disinterested persons, also the warden of the prison, declare that as a mode of execution the electrical plan is far preferable to the scaffold. It is rumoured the Westinghouse Company or some of its adherents spent many thousands of dollars in fruitless efforts to nullify and obstruct the operation of the new law. The ablest lawyers and experts, who ordinarily receive large fees, were employed. The execution of a criminal, whether by the guillotine, the garotte, the gallows, the gun, or the dynamo, is a ghastly business; and it is not surprising that the sensational newspapers, aided by the electrical opponents of the law, should have made the most of such an occasion to fill their columns with revolting details.

The foes of the law dwell upon the fact that the muscular contractions of the victim after the switch was turned prove the correctness of their original position—that Kemmler lingered a few seconds in life, that he was not instantaneously killed, therefore that electricity is a failure for this purpose, and the law should be repealed. We have only to say, if they are not satisfied with the electrical apparatus used at Auburn, if, as they claim, it is not effective, then let us employ the deadly devices which the complainants themselves use, own, and control, with which they fill our streets and slay our innocent citizens. Let them bring the culprit to our city prison, place him on a conducting floor, introduce one of their street light wires, and with it, at the moment of execution, touch the hands of the prisoner. It will extinguish life instantly. It has rarely been known to fail."

Edinburgh  
Exhibition Awards.

A GOOD deal of disappointment has been caused by the decision of the Executive Council, not to give awards in the electrical departments of the exhibition. We understand that this is in consequence of the London Chamber of Commerce and the Institution of Electrical Engineers refusing to appoint a jury. It is not a usual thing for the Institution to appoint a jury, and if it did not care about the task the exhibition authorities should appoint their own. We are aware that a stipulation was entered into with the London Chamber of Commerce on this matter, but if this body backs out the exhibition officials must look elsewhere. At any rate they should act fairly towards the electrical firms, many of whom may have been induced to exhibit in the hope of obtaining some reward in the shape of prizes. Were it not from the fact that awards were understood to be forthcoming the matter would not be worth discussing, for, after all, the value of exhibition medals or certificates is more apparent than real. Probably it was found impossible to get together a body of experts to undertake a series of exhaustive and lengthy tests without paying heavily for their services, and awards for merely showing apparatus give no legitimate representation of the standard of excellence to which the manufactures of any firm have been brought. As the matter stands the proceedings are calculated to render exhibitors more and more averse to participating in "International" shows, into which they are so frequently entrapped by specious promises made under the cover of high sounding patronage, and from which they apparently reap so little benefit.

Yet Another  
Alternator.

IN Messrs. Pyke and Harris's letter, which appears in another column, the principle of the new Thomson alternator is claimed afresh. We have examined the patent specification of Pyke and Barnett, and observe that the machine they refer to is indeed similar in principle to that of Prof. Elihu Thomson. In the application of the principle, however, it rather resembles Kingdon's. The lines of force do not pass through the axle, as in Thomson's, the magnetic circuits through adjacent generator coils being completed by inductor segments attached to rotating wheels. We cannot describe the machine in detail without a diagram, but may mention that it has one magnetising coil wound in two sections, four circles of projecting stationary cores with generator coils on them, arranged two concentrically on each side of the magnet, and two magnetic inductor wheels. As we have shown, the application of this principle is at least as old as 1883, probably older; but

if there is any inventor prior to Lever, who had similar ideas, he has not yet urged his claim.

An Electrical  
Patriarch.

IN a circular card, which Messrs. Sydney F. Walker and Co., are sending out, there is attached the following note:—"Our Mr. Sydney F. Walker claims to be the oldest living electric light engineer in the kingdom, if not in the world, he having been electrician to the proprietors of the first dynamo machine that was introduced into this country." Is not the unbounded assurance of this electrical patriarch appalling? Possibly more than one individual in the profession who would be apt to characterise Mr. Walker's work as the production of the oldest electric light engineer on the grounds that it would not reflect too great credit on the youngest; indeed, we have heard on good authority, that his dynamos bear traces of being built on the lines of "the first dynamo that was introduced into this country." This, however, we cannot vouch for, but we would like to hear from Mr. Walker on what he bases his claim, as we know something of "the first dynamo machine that was introduced into this country."

The Telegraph  
Service.

A MEDICAL man suggests the following remedy for the "address insufficient" grievance, of which those who frequently make use of telegrams are now complaining in the columns of the *Times*:—"Let no message be taken at a telegraph office with a paid reply without receipt of a full and sufficient address from the sender. Let all paid replies be sent to the office whence the first message was issued, and in case of difficulty, let a telegram whose owner cannot be at once found be referred to the post office." The theory that the non-delivery of telegrams is due to the employment of careless boys, whereas letters, which rarely, it is said, miss their destination, are in the hands of experienced and trustworthy men, scarcely explains the matter. If a letter is addressed to "Darwin, Cambridge," the postman probably gives it to the first person of that name he comes across in his rounds, and if it happens to be for another individual, he eventually receives it through the information contained therein. But, in innumerable instances, letters are returned to the sender with "Not known," &c., written across the envelope, so the telegram fault evidently does not lie in the employment of boys in lieu of men.

Fire Office Rules.

WE are all agreed that there should be a standard set of fire rules for electric lighting, but while electricians, like doctors, disagree, we seem as far off this desirable end as ever. Professor Silvanus Thompson lauds Mr. Heaphy and the Phoenix rules to the skies, and suggests their general adoption on the grounds that they have stood the test of time and are workable. Mr. Verity and Mr. Campbell Swinton, both men of practical experience in the wiring and fitting of houses, a matter in which Professor Thompson cannot claim a like advantage, hold the opposite view with very good reason, as a perusal of their letters to the *Times* will show. We agree with these gentlemen so far as their objections to the Phoenix rules are concerned, although we consider that the Institution of Electrical Engineers need not be concerned in the question at all. The desired result should not be difficult to arrive at by a judicious combination of supply companies, contractors, and fire offices, and we shall probably refer to this important topic more lengthily in a future issue.

## ELECTRIC RAILWAYS AND OCEAN CABLES.\*

By T. D. LOCKWOOD.

I HAVE read with a good deal of interest the communication of Mr. Cuttriss, in *The Electrical Engineer* of August 6th, concerning the disturbances manifested in his cable-receiving instruments, which he attributes to the operation of an electric street railway, at a distance of upwards of half a mile therefrom; and with equal interest the editorial comment on said article.

Though it is doubtless often unpleasant to be like Mr. Cuttriss and myself on the physically weaker side of a controversy, that position is not without its offsetting advantages, in that we are forced to study, and let us hope sometimes to master, the problems they involve; while persons working with less delicate appliances and with the electrical pursuits which cause, as distinguished from those which suffer from, the disturbances, are often and naturally content with a perfunctory examination of the matter.

As I have read the two articles, I gather that the disturbed cable circuit comes into the station from the sea conductor, passes through the instruments at the said station and then back by way of a closely parallel insulated conductor in the same cable to earth at the cable armour.

If I have correctly interpreted the arrangement, it is first to be observed that it is not as stated in the editorial comment "a complete metallic circuit," but simply a loop of an earth completed circuit, the two wires of said loop being parallel.

I should scarcely expect that any such disturbances as are described arise from magnetic induction, and in the light of experience do not believe they do, not so much, however, because the wires are looped for a certain distance, as from the fact that in addition to said looping, they are buried; they are underground; both conditions would tend I think to adversely affect magnetic induction.

I am inclined to believe that the disturbances have a twofold cause; that they are partly due, as Mr. Cuttriss suggests, to actual conduction through the intervening earth and water from the earth side of the electric railway circuit to the cable armour, and thence by way of that conductor, which is grounded on the armour, and through the instruments to the cable main conductor; and also in part attributable to the actions and reactions of electrostatic induction, which in such a case are likely to be complicated.

We may consider the earth, if of favourable constitution, to be heavily charged by the electricity poured into it from the cars.

It is not difficult to conceive that such a charge in the medium surrounding the buried cable will tend to attract a like charge of opposing sign, through the dielectric on both conductors of the cable. Thus if the earth be charged to a given plus potential by the railway, the two parallel conductors of the cable loop will both be the recipients of a minus charge. But this charge must come from somewhere, and as the armour earth terminal is nearer than any other, the major part of it comes from that point. But there is another reaction; the two sides of the loop are of unequal length, and it may well be imagined that the charge on the short side, that grounded on the cable armour is thicker, if I may so express it, than is that on the long leg which is but the end of the main cable conductor. The two will tend to react on each other, and the amount of the perceptible reaction will be the difference of the two charges.

But of course, any change in the potential or degree of charge in the surrounding earth, will eventuate in a redistribution, and a rearrangement of the charge in the cable; and such a rearrangement amounts virtually to a circulation of current. And as all changes or transfers of electricity from one side of the loop to the other must pass through the instrument, we necessarily have the undesired operation of the said instrument.

The editorial says: "There will, of course, be a solution for the difficulty, but it will be interesting to see just what it is." The solution of the difficulty is, in my opinion simply the use by either party of the complete parallel wire metallic circuit, imperfectly and at a high cost, by the cable company, whose property is trespassed upon; or in a practically perfect way, at a comparatively low cost, by the railway company, who is doing the trespassing.

## ELECTRICAL SIGNALLING APPARATUS.

IN presenting the report of the Comité des Arts Economiques upon the results of the competition established in 1884, by the Société d'Encouragement pour l'Industrie Nationale, relative to the invention of an apparatus for announcing the passing at a distant point of railway trains, M. Rouselle said the result of the competition had been the bringing to light of several interesting devices, but no definite decision had been arrived at, although the time for fulfilling the conditions had been ultimately extended to 1889; the value of the prize had also been raised from 2,000 to 3,000 frs. The several prorogations which had taken place had been necessary, in order to allow of the exhibits being properly tested by actual practice. The competitors numbered fifty, and many new and ingenious ideas had been put forth, notwithstanding which, only two of the competitors, viz., Messrs. Baillehache and Clémandot, the latter a member of the Société, had been able to establish their claims, M. Baillehache's device consisting of an insulated counter-rail, placed at the point from which the train in movement starts the signal, and in connecting by a wire this counter-rail to the station at which the signal is received, and which is furnished with a battery and an alarm. The springs of a passing train establish a connection between the two rails, and a circuit is formed, which, having traversed the wire connecting the two posts, returns to the earth and is closed by the springs. The alarm is sounded, and not only announces the presence of the train, but also its speed and the number of carriages composing it. A very useful, and even necessary complement of the system, is a controlling wire, by which the circuit is closed when the commutator button at the receiving post is pressed. By this the agent is in a position to satisfy himself that the apparatus is in working order.

M. Clémandot's system, which possesses the important advantage of dispensing with any moveable accessories in establishing the circuit, is based upon the difference between the electric resistances of two lines of rail, according as they are united by the wheels and springs of the train, or they are free. At the signalling point, a battery and an electromagnet are placed at the sides of the line; at the receiving station a relay is established by means of another battery and magnet and an alarm is established in derivation. Two wires form the connection between the two stations. Under ordinary conditions, a continuous current traverses the whole extent of the circuit. When a train is passing the armatures of the electromagnets are displaced, and the normal current is replaced by two local currents, one of which, at the signalling station, is closed by the springs of the train, whilst the other, at the receiving station, traverses the alarm in derivation and sets it going.

Notwithstanding the thorough testing over a period of several years, on various railway lines, which these apparatus have undergone, the committee remains undecided. Both systems, in fact, have been impeached as open to serious objection, sometimes on the score of safety. The committee, however, expresses the hope that so much skill, ingenuity, and knowledge on the part of the inventors will not have been expended in vain. The Society is unable to award the prize to either, but a distribution has been made as a recognition, to some extent, of the value which attaches to their labours.

\* See last week's ELECTRICAL REVIEW.

M. Baillehache will, accordingly, be awarded 1,000, and M. Clémandot 1,500 frs., as it is considered that the latter's system affords the better guarantee of safety, a consideration which the committee judges to be of supreme importance.

### HIGH POTENTIAL STORAGE BATTERIES.

IN one of his early patents, Mr. Faure describes a method of arranging lead plates in such a manner that connectors and separate receptacles can be dispensed with. Plain sheet lead, pasted on both sides with red lead, is packed between elastic frames, constituting three sides of a cell open at the top. The space thus produced between the plates is filled with the electrolyte, the first and last electrode of a series of such cells being then connected to the source of supply. With the exception of the end plates, each intermediate electrode will become negative on one side and positive on the other. The capacity (in ampère hours) of such an accumulator is necessarily limited to the dimensions of one plate, and the electromotive force is proportional to the number of plates. A similar battery has recently been invented in New York, called the "Dey Series High Potential Storage Battery." Mr. Dey uses a hard Indiarubber case made of sheets which are screwed together. This is lined with a soft rubber box having ribs running down the sides and across the bottom. The lead plates, which have a raised rim, slide down the grooves formed by these ribs, and when the side is screwed on it forms watertight joints between the ribs and plates. The plates are made grid fashion, with a web or partition down the centre and projecting half-an-inch above the active material to keep the acid separated. The active material is applied in the form of a dry powder, red lead being placed on the positive side and litharge on the negative. The plates are 9 inches by 15 inches by  $\frac{7}{16}$ ths thick, placed  $\frac{3}{8}$ ths inch apart. A complete cell containing eleven whole plates and two half or end plates, has a normal output of 94 ampère hours, and an E.M.F. of 24 volts, and it weighs 210 pounds. This does not show any advantage over existing types with separate cells, which are preferable for various reasons. Mr. Dey has a novel arrangement for cutting out of circuit the battery when fully charged, somewhat, we think, on the lines of an apparatus used in the old Colchester installation. This cut-out consists of an inverted U-shaped tube which is filled with acid and suspended on the plate. The gas from a fully charged cell rises into the tube, displaces the acid and thus causes the tube to move upwards against a spring making contact with the apparatus which operates the cut-out. The Sawyer-Man Electric Company use two series of six cells in their photometer room, giving an E.M.F. of 144 volts. Plates of this description will necessarily buckle, as the positive side alone expands. Concerning this defect, Mr. Dey maintains, "that when they do buckle (which occurs rarely) they all buckle in one direction (positive side out) and fit into one another like saucers." It must be an interesting sight after, say, a year's continuous work, if the arrangement can hold out so long.

### THE RELATIVE POSITION OF GAS AND ELECTRIC LIGHTING.

IT may perhaps be interesting if we refer to the relative present position of gas and electric lighting, and in order to do this we must review the status of the two illuminants during the past three years. In 1887, 1888, and during the first half of last year, gas companies, and the supporters of the older light regarded with indifference the gradual increase in the use of the electric light, and the consensus of opinion arrived at by them was that there was not the slightest fear that electricity for illumination purposes would be a formidable competitor of gas. Statements to this effect were frequently

made at the meetings of the gas companies, and the shareholders were assured that the possibility of the use of the electric light acting detrimentally to their undertakings was entirely out of the question. As time passed away there came into existence numerous companies for lighting by electricity the most remunerative—to gas companies—London districts and provincial towns. In some instances the gas companies opposed the applications made by electric light companies for Parliamentary powers, but their opposition was unsuccessful. Such was the state of affairs some time ago.

At present, however, the position is entirely changed. The inauguration of new central electric light stations, and the erection of others throughout the country, have caused some gas companies to recognise the fact that the electric light is not only a competitor, but that it is also gradually superseding gas in many large establishments, which were formerly considered among the most profitable customers to the gas companies. To show to what extent this condition now prevails, we may mention that in the metropolis alone the two largest companies—the Gas Light and Coke and the South Metropolitan—have sold considerably less gas during the half-year ended June 30th than in the corresponding half of last year. The amount of the dividends paid has also diminished, that of the former company being 13 per cent., as compared with  $13\frac{1}{4}$  in the corresponding half of 1889, and that of the latter being 12 per cent., as against  $13\frac{1}{2}$ . Moreover, the Gas Light and Coke Company found it necessary some time ago to increase the price of gas by 3d. per thousand. In these two instances the diminution in the consumption is, of course, not considered by the companies concerned to be due to the competition of the electric light; but it is significant that they are seeking new openings for the use of gas—a fact which leads to the conclusion that the two companies are fully aware that in certain districts they cannot possibly expect to increase the sale of gas for lighting purposes, and that the diminution already taken place must to a certain extent be attributed to the gradual adoption of the electric light by those who are prepared to pay for it. Again, the directors of provincial gas companies no longer consider their position impregnable, and they are therefore following the example of the London companies by endeavouring to extend the uses of gas, and at the same time keeping a watchful eye on the progress of the "coming" light.

It may appear surprising that the shareholders in gas undertakings should take the trouble to ascertain the position of the electric lighting industry; yet such is the case. We know of instances where the holders of gas stocks have asked financial journals, representing the gas industry, to explain the present position of the electric lighting business in so far as it related to the supply of gas, in order that they might decide whether to increase their shares or otherwise. Actions of this kind distinctly indicate the feeling of distrust on the part of some gas shareholders, for although in some instances where the electric light has been introduced the consumption of gas has augmented owing to its being used for other than lighting purposes, yet in others the reverse has been the result.

It would appear from this that the use of gas for lighting is slightly diminishing, but that for cooking and heating and motive power purposes it is increasing. It is therefore in these directions that gas companies will be able to augment the consumption, and to these three branches great attention is being devoted. The days of the "no competition" theory have passed away, and it is satisfactory to find that many gas companies realise the important fact that, notwithstanding its higher price, many consumers prefer to have the electric light.

**English Lighting Companies Note.**—The Continental Edison Company, which has a nominal capital of £400,000, actually supplied current during July in Paris to the extent of £3,220 gross.

## COMPRESSED AIR FOR THE TRANSMISSION OF POWER.

THE transmission of motive power by means of compressed air on the "Popp" system—an ominous name for English ears—is exciting some attention in Germany where efforts are being made to represent it as equal, if not superior, to the electric transmission of power. The report of Prof. Gusinde in favour of electricity, is being criticised by officials of the Berlin Compressed Air Company, and the respective assertions of these rivals are given by the Berlin *Finanzherald*, which seems to have a manifest leaning to M. Popp and his scheme.

As a specimen of the style in which this controversy is being waged, we may quote the following passage from Prof. Gusinde's report, followed by the reply of the Poppers. Says Dr. Gusinde—we believe with full truth: "In America, where numerous electrical central stations are at work, the compressed air system has nowhere found admission, whilst the electrical transmission of power has been for a long time introduced for all trade purposes and is continually growing in extent and importance. It may be here mentioned what prominence the electromotor has obtained in America in tramlines, whilst the air motor cannot undertake a competition in this promising region."

If this is true, it is an important piece of evidence against compressed air transmission. If it is not true, it is the duty of the Popp Company to show *when* and *where* air tramlines have been in successful operation, and what, if any, are their advantages over electric lines.

Instead of so doing, the Popp Company merely reply: "Tramlines with air-propulsion have been at work for some time." Where, and with what result, the reader is left to guess. They add: "It is therefore the duty of a serious critic to take the results of these air-tramlines into consideration." Surely, it is rather the duty of the Popp Company to adduce—if they can—any facts calculated to refute the statements of Prof. Gusinde.

Again, said the latter *savant* in his report: "The superiority of the electrical transmission of power is hence demonstrated." The reply is, "that the superiority of the electric transmission of power is not proved!" Here the Popp Company ought to have shown, or tried to show, some superiority on their side. But no attempt of the kind is made. Surely a different style of advocacy is needed to secure a favourable verdict from an educated public!

## WHAT CONSTITUTES A DANGEROUS ELECTRICAL CURRENT?\*

By NELSON W. PERRY, E.M.

## PART I.

THE question is continually arising as to what is a dangerous current of electricity, and the answers that may be encountered are usually so varied that the enquirer is prone to ask again with the result as unsatisfactory as before, and a conclusion that the electric fluid is as mysterious in its effects upon life as it is to most people in its other manifestations.

It would not be far wrong to state that the most general feeling in regard to this question at the present time is that, a given current might kill to-day and be harmless to-morrow; that what would be certain destruction of life to one individual could be safely borne by another. In fact, such a belief is but a consequence of that very common opinion among the laity that electricity is not amenable to infallible laws like other forces, or that if it is, then such laws are at present but imperfectly understood.

Such, however, is far from being the truth. It is

indeed very common to hear the statement that we do not know what electricity is—but how often do we hear the statement that we do not know what gravity is?

How many of us if asked the question would hesitate for a moment in stating that we were in possession of full knowledge in regard to gravity and yet at the same time would delegate electricity to the unknown, and perhaps to the unknowable? And yet of the two, much more is actually known to-day about electricity than is known about gravity. In fact, the electro-magnetic theory of light so beautifully formulated by Clerk Maxwell has received at the hands of Prof. Hertz within the past two years, experimental demonstration, and we know beyond peradventure that electricity is a phenomenon of the ether in the same sense as light is.

We cannot say that we know all the laws of light—we know a great many of them—in fact, nearly all that are necessary to explain the phenomena with which we are confronted, and we find that these laws are all absolute in their workings—they are infallible.

So it is with electricity. If we do not yet know quite what it is, we are certainly much nearer a solution than we are in the case of gravity. It would be folly to say that we know *all* the laws of electrical action, but we probably know even more of its laws than we do those of light, and they are in no way less certain. In fact scientists have long since come to the conclusion that the laws of nature are all infallible. It is a fundamental doctrine of science that under like conditions like results must inevitably follow. There are no miracles in science; there may be mysteries, but they are mysteries because of our ignorance of the conditions, and not because of the abeyance of any of nature's laws. The difference between the scientific mind and the unscientific mind is that if an apparent contradiction of an accepted law is noted, the former assumes some condition not understood, and the latter immediately assumes it to be what it appears, viz.: A direct contradiction of the law.

To the latter such a thing is not so very remarkable—the world is full of just such contradictions; it is therefore not inconsistent with previous experience, and it does not even excite surprise. To the scientific mind, however, such a thing as the fracture of a law or its abeyance for one instant is an utter impossibility and unthinkable.

Electrical science to the unscientific mind may logically be a department of contradictions; but to the electrician it is one of fixed and inviolable laws as are all the other sciences; and what is more it has arrived at a position of an exact science in which results can be predicated from given data with mathematical exactitude and precision. In fact astronomy does not rest upon a more sure mathematical basis than does the science of electricity.

Electricians are sometimes asked to explain many things that never occurred; for instance, it is universally acknowledged that 110 volts—that usually employed in the incandescent light is perfectly safe as far as life is concerned. Yet not long ago it was announced all over the country that a little coloured boy was killed at Chattanooga by coming in contact with an incandescent light wire of 110 volts, and electricians were asked to explain how this could happen. It could not be explained, and was not until the coroner's inquiry developed the fact that no electricity had been on the wire for over a half an hour previous to the boy's coming in proximity to it, that the boy did not die from an electric shock, and that the burns that were attributed to the electric current were due from an oil lamp which the boy had in his hands, and not to the electric current.

And then supposing the statement were true, and it is not questioned anywhere, that a current of 110 volts such as is usually employed in incandescent lighting is perfectly safe, yet it is not true that it is safe to touch every incandescent circuit one meets. Most of our electric street cars are operated by a current of 500 volts pressure. In all such you will observe five electric lights, similar to those you see in the stores. Now while each

\* *Western Electrician.*

of these lights is only called upon to stand a pressure of about 100 volts, they are placed in a row or in "series," so that the same current passes through each in succession, and meets with the combined resistances of all of them. In such a circuit five lights of 100 ohms each resistance can be opposed to a pressure of 500 volts, and yet the effect would be to subject each individual light to a pressure of one-fifth the amount, or 100 volts. One can, however, take his choice of shocks due to 500, 400, 300, 200, and 100 volts, according as he short-circuits five, four, three, two lamps, or only one.

In case an electric road were operated by a current at 1,000 volts, it is evident that ten 100-volt lights could be operated in series in each car, and under these circumstances the seeker after sensations could get anything he wanted in the way of shocks from that due to 100 volts pressure up to that due to 1,000 volts pressure. That it is quite evident that while the first statement might be perfectly true if comprehensively understood, yet it would not be advisable to assume that all incandescent light circuits, or even all circuits containing 110-volt incandescent lights were safe. And again, as we have seen that in the 1,000-volt circuit all pressures from 100 volts to 1,000 could be obtained according to the point where one touched the wire, so it would not be safe to assume that because I touched the circuit with impunity at one point you or anybody else could do the same at another point. And yet this is just what would be assumed by the majority of people, and if you were killed, and I was scarcely shocked, it would be referred to as an illustration of the idiosyncrasies of the electric current.

A couple of summers ago I was present at the starting of a new electric underground railroad in one of the coal mines in Pennsylvania. The trolley wire—to use an Irish bull—was a light T-rail, supported on timbers overhead out of reach of persons standing on the ground. At one point there was a switch by which the current could be turned on or off, and on this day, as it was desirable to have this readily accessible, a large wooden block was placed on the ground underneath it. By standing on this, one could readily reach the trolley rail and switch. Had the block been a perfect insulator, a person standing upon it could have touched the trolley rail without the slightest shock, even though there had been 5,000 volts instead of 350, as was the case; but as it was, the conductivity was just sufficient to give one standing upon it, and touching the rail, a right smart shock, and the whole thing being new to the miners, they were amusing themselves by getting up and touching the rail.

One man, thinking to have a little fun at the expense of another, jumped upon the block, and while he touched the rail with one hand, grasped his intended victim, who was standing on the damp ground, with the other.

He thought to surprise his friend with a slight shock, such as he himself had been taking in fun before, but the joke was a huger one than he had anticipated, for, by grasping the other man's hand, he made a good connection with the ground, through his own as well as his friend's body, and the result was that both men were violently thrown to the ground, and so quickly, that they scarcely knew what had done it; neither man was hurt, but all had a great respect for that trolley rail thereafter.

Not many days from this time, a mule came in contact with this same trolley rail, and was almost instantly killed, and in falling he pulled his mate over in contact with it, and he, too, was killed. Now here were three different effects from the same current, yet the conditions being different, the results varied widely.

Now, if we were to try to reason by analogy, we should say—this current was strong enough to kill two mules, therefore these two men ought in all fairness to have been killed. But they weren't.

Again, among the miners it was argued that since one man alone on the block could easily stand the shock, and two men catching hold of hands were both thrown to the ground, if three or more had hold of each other, they certainly would have been killed.

The electrician readily sees the fallacy in the last argument, but he does not see how the mules should have been killed while the men escaped. He merely knows from numerous instances, of which this was one of the first recorded, that mules and horses are very much more susceptible to electrical influences than is man. Why, he does not pretend to say any more than he does why a pig will fatten on arsenic or antimony which are fatal in small doses to man. The physician can tell, perhaps, but not the electrician, and the physician had to learn the fact from experience; there was not a *priori* reason why it should be so.

This calls to mind an amusing story that I once heard as to the origin of the term "Antimony," which is the name of a metal closely resembling arsenic in many of its properties.

Some monks had found a new mineral and had prepared from it a new metal, which, so far as they could see, proved to be utterly worthless, so they threw it away. It fell within reach of some of the hogs belonging to the monastery, and the monks noticed that they devoured it with apparent relish. Curious to know the effect of such a diet upon the swine, they fed them regular with it for some time and found that they not only prospered, but grew enormously fat upon it. Some of the monks reasoned that if it was so good for the hogs it ought to be good for themselves too, so some of them partook of a liberal dose of it, resulting in their speedy horrible death by poisoning. The new metal was therefore called "Anti-Moine," which by slight change has become Anti-mony.

The authenticity of this origin for the term is very seriously doubted, but the story serves to illustrate that the fact that 350 volts is fatal to a mule while it is not to man, rests upon the same experimental data that the other fact does—viz., that a hog can eat some things with profit that are not conducive to longevity in man.

Now, while I know of no *priori* reasons why a certain quantity of electricity should be fatal to man, still I believe it to be an established fact that the quantity that will be immediately fatal can be fixed with as much certainty as can the fatal dose of any of our well-known poisons, and I think it is now surely settled that a single ampère of current caused to pass through the vital part of the body is much more certain to be instantly fatal in all cases, and, in any case, than is hanging by the neck; and I think the question "is hanging necessarily fatal?" much more doubtful than is the other one—"is one ampère of electricity necessarily a fatal dose?" and the answer to both of them is "Yes, if properly applied."

A man may be hung by the neck without breaking it, or he may be hung by the hand or by the waist, and if not kept suspended too long, there will be little danger of death. So may a man take one or several ampères of current through the hand or leg or foot, or other non-vital portion of the body, and be not permanently disabled, but I do not believe that it is possible for him to take one ampère in such a way that the brain or the heart are in the direct line of the current without instantaneous and painless dissolution.

It has for a long time been generally admitted that one ampère of current, if properly applied, was considerably in excess of that required to produce instant death in man—there has practically been no question as to that, but the question has been how great a voltage was necessary to ensure the passage of an ampère of current through the body. It has been supposed, and there has been much testimony adduced in support of the supposed fact that the resistance of the human body, and therefore the electromotive force necessary to drive a given quantity of electricity through it, was such a varying and variable quantity that measurements made of the resistance of certain individuals at one time were of absolutely no value in the case of other people, or even in case of the same people at a different time. In fact, there seemed to be some ground for believing that the human body offered very different resistances to currents of different potentials, and if this were so, a determination of the resistance to the milder currents, that could be used without disagreeable con-

sequences, would be of absolutely no value in arriving at the resistance that would be opposed to currents of higher pressure.

The importance of knowing the resistance of the human body at the time of experiment is essential in arriving at either the number of ampères that a given electromotive force will drive through it, or the number of volts that are necessary to force a given number of ampères through it.

As late as last summer, there was nothing but the most contradictory evidence on this all important point, if we are to take the evidence of electrical and medical experts who appeared before referee Becker in the Kemmler appeal.

One expert found, upon testing the resistance of a certain electrician, these results :

With a current of 1 volt the resistance was	6,300 ohms.
" " 10 volts " "	5,140 "
" " 50 " "	3,850 "
" " 100 " "	3,500 "

The current was passed from one hand, through the body, to the other hand, perfect electrical connection being provided for by moistening the hands with a solution of sulphate of zinc. These experiments seemed to indicate that as the electromotive force increased, the resistance of the body decreased.

Next a newspaper man was tried. Connection was again made by means of a solution of sulphate of zinc, but in this case the current was passed from the head to the feet. As was perhaps to be expected from the subject, the average resistance was much greater.

In the first experiment it proved to be	7,097 ohms.
" second " " "	6,297 "
" third " " "	6,092 "

Newspaper men are proverbially early risers, but the electrician is not to be outdone if he knows himself, so the next witness to testify was an electrician who had tested his own resistance from hand to hand with the following results.

Using the current from one cell, his resistance was 80,000 ohms.

Using the current from 10 cells his resistance was 37,000 ohms.

Later, using the current from one cell, his resistance was 31,000 ohms.

Later, using the current from 10 cells, his resistance was 24,500.

Two minutes after using the current from one cell, his resistance was 36,000 ohms. Using the current from 10 cells, his resistance was 21,500 ohms, and in the final tests with one cell, he found his resistance to be 21,600 ohms ; with 10 cells he found his resistance to be 16,000 ohms.

These figures seemed to show two things—first, that, as the electromotive force experimented with increased, the resistance of the body decreased ; and, second, that, in a series of experiments following each other in rapid succession, the resistance very rapidly decreased.

The significance of these figures is apparent when we remember that, in order that one ampère of current shall be forced through a resistance, the electromotive force, measured in volts, must exactly equal the resistance, measured in ohms.

Thus, from the preceding testimony, we find a variation in resistance from a maximum of 80,000 ohms, which would require an electromotive force of 80,000 volts, if one ampère is the current required, down to a minimum of 3,500 ohms, through which it would require a pressure of 3,500 volts to force the same current—a variation between maximum and minimum of nearly 2,300 per cent., and in the case of the same individual, at different times and different potentials, a variation from 80,000 to 16,000 ohms, or 500 per cent.

It is evident, if these figures are reliable, no value whatever is to be attached to measurements made at one time in determining what the resistance would be at another.

It was known that the skin offered the greatest resistance to the passage of the current, and it was readily

surmised that in different individuals greater or less callousness might be responsible for very great variations, and in the case of the same individual it was readily to be conceived that the difference in the condition of the skin as regards moisture might have a controlling effect in the measurement of the resistance of the body, and a moistening of the hands with a solution of sulphate of zinc—a good conductor of electricity—was resorted to in the first two cases cited, to remove this difficulty as far as possible, and to insure better contact. But zinc sulphate is a powerful astringent, and has a tendency to harden the epidermis and prevent its absorption of moisture, or its exudation in the form of perspiration, and, as might have been foreseen, failed to accomplish the object for which it was intended.

Thomas Edison had foreseen the objection to the use of sulphate of zinc, and also another, viz., that it would be totally impotent to remove the insulating effects of the oily exudations of the skin, and in other respects, since the resistance would depend very much on the tightness with which the electrodes were grasped by the person, it would be very difficult to obtain the same conditions with two different persons, or to maintain them the same with the same individual during two successive experiments.

So in his experiments to settle the question in his own mind as to the resistance of the human body he chose a liquid for moistening the skin that was not only not an astringent, but rather the reverse, and which at the same time was deterative and would saponify the grease.

In a solution of caustic potash he found just such a fluid, and he eliminated the uncertainty due to the variability of pressure upon the electrode by causing his subjects to place themselves within the circuit by immersing each hand in a metal jar of this solution which was connected electrically with his battery.

Following this method, by which he sought to maintain his conditions more uniform, he tested the resistance of 250 subjects—probably by far the largest number that has ever been tested under even approximately similar conditions, and found *their average resistance* to be 1,000 ohms, and out of all this number the extremes were 1,800 and 600 ohms.

He also found that the resistance of the same people at different times was practically constant—the maximum variation of the same individual at different times was 50 ohms, or 5 per cent. of the average resistance.

Thus we see order again brought out of chaos.

The experiments have since been repeated, though not on the same scale, with results so concordant that it is now considered a pretty well settled fact that the human body does not vary more widely in its behaviour toward electricity than it does toward other things—drugs or poisons for instance, and the normal resistance of an adult body is a pretty well-fixed figure, and the maximum variation from the figure as determined for the individual does not exceed 5 per cent. under ordinary conditions.

## ELECTRICITY IS LIFE.

It is said, although we confess that we have not yet experienced the sensation, that before a thunderstorm everything has been so still for days that the oxygen in the air has been to some extent deprived of its life-sustaining power, and a feeling of drowsiness comes over all. The air has been partially devitalised, and is not fit to produce in man to the same degree the usual vitalising effects. But the lightning flashes restore the lost energy to the oxygen, and a feeling of exhilaration is experienced after the thunderstorm is over. "What the electric flashes effected in the devitalised air of the chamber in which the experiments on the animals were made, the lightning effects in the weakened air during sultry close weather ; vitalising power is restored to it." The quotation is taken from a contemporary, in which certain experiments on animal life are described as

follows:—"After several animals had been breathing in a chamber of pure oxygen, Dr. B. W. Richardson collected the gas in the chamber and freed it from all but the oxygen, so that no chemical test was able to show any difference between its character and composition and those of freshly-made oxygen gas. When he passed this purified oxygen for the second time into the chamber, the animals soon became drowsy, and on repeating the experiment by successive purifications of the exhaled air the animals died. He concluded, then, that oxygen which had been repeatedly passed through the lungs of warm-blooded animals, however thoroughly purified from carbonic acid, watery vapour, and ammonia, no longer maintains life. It has become what is scientifically called "devitalised." But the startling discovery still remains. He passed through the devitalised oxygen currents of electricity from a set of brushes connected with the positive pole of a frictional machine, and the gas had its vital energy restored; animals again lived in it with the customary sprightliness. He discovered that electricity restores to its vital state oxygen which has been rendered noxious by passing through the lungs of animals."

We are not aware whether these experiments are of recent date or not, but they are sufficiently remarkable to lead to the hope that the subject may be pursued further, for they appear to have a direct bearing upon our vitality, and suggest uses in domestic life for the frictional machine such as have not yet been heard of.

Equally suggestive are the results of applying electrical treatment to milk which, as is well known, tends to grow acid during thunderstorms. An Italian, Professor G. Tolomei, has lately tried to throw some light on the nature of this action. He experimented with electricity on fresh milk in three different ways—first, by passing the discharge of a Holtz machine between two balls of platinum inserted nearly two inches apart in a bottle containing milk; second, by sending a battery current between two strips of platinum at the bottom of a U tube holding milk; and, third, by subjecting milk in a test tube to the action of a strong battery current through a silk-covered copper wire wound spirally round the tube. In each case the acidulation was delayed, not hastened. Three equal portions of milk from the same milking, thus treated, began to grow acid on the seventh, the ninth, and the sixth day respectively, while milk not treated with electricity was manifestly acid on the third day. The electrified milk (unlike milk that has been heated to a high temperature, then cooled), coagulates naturally, or by action of rennet, just like ordinary milk. Having thus seen that electricity could not be the direct cause of acidification of milk, the professor next tried the effect of ozone, and found it distinctly acidifying. In one case the surface of a quantity of milk was brought close under the two balls of a Holtz machine, and the milk soon became acid in consequence, the sooner if the discharge was silent (not explosive), in which case more ozone is formed. In another case ozonised oxygen was made to bubble up through a quantity of milk, which in a few hours was completely acid and soon coagulated spontaneously. Professor Tolomei is of opinion that oxygen probably also promotes lactic fermentation (a point which has been disputed). If milk keeps longer in wide, shallow vessels, that is probably due, he thinks, to the cooling produced by evaporation, which is favoured by a wide open surface. The only thing now required is that the same treatment should be applied to the purification of alcoholic drinks, in which at times people are apt to indulge too freely in the belief that good spirits promote a happy state of being, a judicious mixture of milk and spirituous liquor at early morn being calculated to bring about the desired effect.

**Acknowledgment.**—Through an oversight, the source from whence we derived the description of Mr. Field's telephone (*Electrical Engineer*, of New York), was not acknowledged in the article last week; we hasten to express our regret.

## ELECTRIC TRACTION DATA.

AMONG the first and most exhaustive power tests with electric cars were those made by Mr. A. Reckenzaun some three years ago in the City of Philadelphia, and they were published recently in a paper bearing the title of the present article. No less than three well trained men were required for the purpose of making observations, and recording them. Thus, on one occasion, during a run of 43 miles, 7,500 ammeter readings were taken, which had to be written down at the rate of 20 per minute. Considering the very rapid variations of the currents used on uneven tracks, it is absolutely necessary that readings should be recorded in the shortest possible intervals, so that a correct average may be estimated. This process is extremely tedious, and liable to error, in spite of the greatest care of a skilled hand and eye, and many have been the attempts to devise an apparatus which should automatically record the power consumed on an electrically propelled vehicle. The jolting of a car has very little effect upon the extremely light needle of a dead beat ammeter; but the introduction of a pen or pencil must produce deviations due to the momentum of such moving parts of the instrument.

The *Electrical World* of the 16th inst. contains a description of a recording ammeter devised by Messrs. Hulett and Larned, which has been used in recent tests on the Thomson-Houston road at Syracuse, N.Y. This instrument is not free from the objections we have mentioned, yet it appears to have answered its purpose to a sufficient extent to give very approximate values. This apparatus consists essentially of a solenoid 7 inches in diameter, containing 80 turns of copper cable, through which the maximum current of 150 amperes may be safely used. The solenoid is fixed vertically upon a board, and it contains a movable iron core  $1\frac{1}{4}$  inches in diameter, which carries a pen at its upper end. This pen presses against a strip of paper upon a drum, which rotates by means of clock work. The magnetic attraction exercised by the solenoid upon the iron core is balanced by a spring, whose tension is so regulated that a pull of 10 lbs. will produce a deflection of 3 inches; the object in providing so great a force was to render negligible the friction of the core against the bobbin, and of the pen upon the paper and vertical guides. The circumference of the paper drum is 24 inches, and it rotates once an hour; the space allotted to record the variations is 2 inches for every five minutes, and this was scarcely sufficient, the vertical pen strokes due to the current changes coming in some cases too close to each other to render them distinguishable.

In order to obtain the mean ordinate for a whole day, it was necessary to integrate with a planimeter the space included between the curve and the zero line; thus the area was found which, divided by the length, gave the mean height of the diagram. As the movements of a core within a solenoid are not proportional to the current, the instrument was integrated in three parts, and each portion read separately from the calibration curve. The results thus obtained were considered to give a very close approximation to the truth. The object of these tests was to obtain (1) the efficiency of the station, (2) the efficiency of the line, (3) the efficiency of the cars. Ammeter and voltmeter readings were made every 25 minutes at the same time, while indicator cards were taken from the engines. The efficiency of the station gave an average of 62.8 per cent., i.e., the ratio between the electrical H.P. and the indicated H.P. The highest efficiency observed was 82 per cent. when the I.H.P. was 108; but when the I.H.P. dropped to 30 or below, the resultant efficiency did not exceed 40 per cent. The efficiency of the line was calculated from voltmeter readings taken at the station and line simultaneously, and averaged 91 per cent. Seven cars were on the road during these experiments.

The mean efficiency of the cars (motors and gearing) was calculated from observations at various speeds,

and found to be 65 per cent. The efficiency of the entire system, therefore, from the product of these results, amounted to  $62.8 \times .91 \times .65 = 37$  per cent.

The coal consumption has been ascertained to be 4,800 lbs., and since the average I.H.P. throughout the day amounted to 51.4, the coal used came to 5.3 per I.H.P., and 8.4 per E.H.P. per hour. If the plant had been run up to its full capacity, these figures would have been considerably reduced. As the cars ran 98 miles per day, the electrical energy per car mile did not exceed .82 horse-power hour, and one point incidentally noticed in taking volt readings on the line demonstrated the fact that the curves consumed more power than the grades.

About a year ago, Dr. Louis Bell made some tests on the Sprague road at Lafayette, Ind., and showed that the average efficiency was but 25 per cent., 37 per cent. would thus show a considerable advance in the direction of economy of power. Probably this record will be beaten at no distant date.

### THE LIVERPOOL ELECTRIC RAILWAY.

IN a few months there will be opened in Liverpool the overhead railway worked by electricity, which will occupy the proud position of being the first of its kind attempted in England. Last year a few Liverpool merchants met together to discuss the advisability of erecting a railway which would meet the wants of a rapidly-growing traffic. As a result, it was decided to commence the erection of an overhead railway worked entirely by electricity. It was not until the close of the year, however, that operations were fairly commenced. Now the work is being pushed on with great rapidity, and many of the girders are fixed in their places.

The railway, when completed, will consist of a wrought iron viaduct about six-and-a-half miles in length. Columns, composed of two channels and rivetted plates, support the superstructure. Stations are to be placed every half mile, at the points where the population lies thickly, from thence any place on the line will be reached in a few minutes. It is the intention of the company to charge very low fares so that the line may become popular; seeing that it will traverse a working district, this is perhaps necessary, for the revenue will probably be obtained from the lower class fares. The structure will certainly be the finest of its kind, and, as a viaduct, is the longest in the world.

The exact system of electrical propulsion is not yet defined, but there is sufficient guarantee as to the soundness of the technical work when it is mentioned that Sir Douglas Fox and Mr. J. H. Greathead are the engineers.

### HIGH SPEED IN ENGINES FOR ELECTRIC LIGHTING.

By ROBERT H. THURSTON, Director of Sibley College,\*  
Cornell University.

JUST a century ago, the "perfected" steam engine of James Watt had fairly conquered its place as a motor and as the great source of power for the growing industries of the world. Although Watt was not "the inventor of the steam engine," as he has been so often and so generally denominated; and although Newcomen and Cawley were its inventors, if we consider the steam engine as a train of mechanism, and not the old eolipile forms, as the germ of the modern machine; Watt, as the great improver and introducer of the engine, deserves all the honour that later generations have accorded him. The invention of the details of the modern engine was sufficient to entitle him to all

this, even had the machine done vastly less for the race than it has actually accomplished; but the benefit conferred was largely through the action of secondary and resultant developments. The wonderful expansion of the world's industries during the intervening century has been very largely, if not mainly, due to the provision, by Watt and his contemporaries and successors, of a powerful, convenient, economical and manageable source of power. The most striking phenomenon of the century, to the social and the political economist, has been this enormous development of a thousand new industries, of many thousands of new products of industry, and the extraordinary diversification of the skilled vocations of mankind. All this is to be recognised as consequent, very largely, upon the production by the great inventor of a suitable source of energy and power.

Since the days of Watt, there has been no industrial development even approximately as important as the now familiar and almost matter-of-course introduction and extension of the various applications of the power of steam through the intermediary of the electric current as its strong and far-reaching right arm. The growth of steam engineering during the last decade or more has been almost as great and as wonderful as during the earlier days of the development of the Watt engine. The use of the electric light and of electric power transmission, as in the use of motors and on street railways, and the many minor applications of electricity have compelled the expansion of many old lines of business most remarkably, and have accomplished even more remarkable things in the institution of new kinds of production. The glass-blower has been called upon to produce innumerable new forms, and to resort to numberless new and ingenious processes, to meet the exacting demands of the engineer; the worker in brass and in bronze, in fine iron work and in all departments of light tool-work, has been called upon to modify and to improve his methods, and to invent and apply a thousand new devices to the purposes of this latest of all the departments of engineering.

The maker of wire has been forced to seek the finest and purest copper, and to draw it into wire, harder, stronger, and in greater lengths, than it was ever before supposed possible to secure; new kinds of insulation, new systems of support and of preservation, have come into use, each improvement bringing after it a long train of minor or accessory inventions, discoveries, and improvements. Innumerable new forms of dynamo-electric machines, each specially and precisely adapted to a certain prescribed purpose, generators and motors of once unimagined perfection and efficiency; with, for each one of them, a host of little improvements and inventions in detail, have set the world agog with their work, have made the engineer wonder at their ingenuity, and have puzzled even the man of science and the professional electrician by the delicacy and subtlety of their theory, and by the variety and singular characteristics of their interacting currents and forces.

Finally, the steam engine itself has been given new forms to meet the requirements of this imperative new master. We propose briefly to consider the latest modifications of the engine, giving a concise and untechnical account of its special peculiarities, and the principles of its construction and application, as dictated by the new purposes to which it is sought to apply it.

There are two principal characteristics that distinguish the machinery employed for electrical distribution of energy from most other kinds of apparatus driven by the steam engine. The speed of rotation is unusually high, and the regularity of its motion, to insure satisfactory results, must be made extraordinarily perfect. To these two essentials all other considerations are subsidiary. In the various forms of machinery employed in the arts, outside this department, the first demand of the prime mover is generally economy of operation, and the exactness of its motion is a secondary, though often important, desideratum. In the most exacting work, that of cotton machinery producing fine goods, it has been thought that the regulation of

\* *Electrical World.*

the engine driving it should be made sufficiently perfect to keep the fluctuations, with usual variations of loads, within about one per cent. of the mean and within a total range of two per cent.; but, in electric lighting machinery, the range considered allowable is oftener half these figures, and some makers guarantee that the fluctuation shall be imperceptible, from full load to no load. The usual speed of the main line shafting in mills and in shops is rarely above 200 turns per minute, while, in the dynamo, the range is from about 1,000 on those of moderate size and of special types, up to 2,500 and 3,000 in extreme cases; while some are constructed to turn very much faster than the latter, even. The engine demanded of the trade for these latter purposes, therefore, must be capable of regulation to within perhaps one-half the range of the older types, and must be fitted to couple directly to machinery having five or ten times the speed of rotation of ordinary mill machinery. This demand, exacting as it is and seemingly impossible to meet, as it would have been thought not many years ago, has been satisfactorily fulfilled by a number of inventors and constructors.

The difficulties to be encountered in the attempt to comply with such conditions can hardly be realised by those unfamiliar with the steam-engine and its development. It was at once evident that the speed of rotation must be increased, and the ideas of Charles T. Porter, who had, as early as 1860, shown that speed is an element of economy, and had begun to exploit a "high-speed" engine, seeking economy in that manner, were recognised as elements of the new form of engine. In the days of Watt, the speed of rotation had rarely, even with small engines, exceeded 50 revolutions per minute; and Mr. Corliss considered that a speed of 75 revolutions was about as high as his tripping mechanism would ordinarily allow; but Porter went up at once to 200, and the Corliss engine is now sometimes driven at over 100 revolutions per minute. The modern high-speed engine goes far above these figures, however, and 300 revolutions is thought a very fair, but not radical, limit. In a few cases, as in engines of Ericsson and others built for special applications, this speed has risen to as high as 1,000, and even, with very short strokes of piston, experimentally to over 2,000.

Some of the conditions of success in the attempt to solve this great problem are sufficiently evident.\* The obviously essential high speed of rotation of such engines can only be attained by simplifying the construction of the machine just as far as practicable, and by discarding the "trip cut-off" and adopting some "positive motion" valve gear. But the trip was considered the vital element in the regulating mechanism of the older engines, as it allowed the governor to do its work without introducing irregularities in its action through resistances coming from the valve motion. Porter adopted a "positive" and then secured good regulation by use of the powerful loaded governor, in the form now so well known by his own name. Harnell and Guthrie, the inventors of the device in England, and Hoadley, the first to use it in this country, by adopting the now almost universally employed "shaft governor," gave to all later makers the means of solving this problem most satisfactorily, enabling them to use the simplest possible valve gear and yet to obtain a good distribution of steam and the most perfect regulation at the same time—conditions formerly considered absolutely incompatible.

It is practicable to make the "detachable" valve gear operative up to speeds even exceeding 100 revolutions per minute; the shaft governor is adapted to velocities of 200 turns and upward; the higher the better. At 300 revolutions a minute, a common speed with this class of machine, it is possible to regulate, by nice adjustment, to within a range of one-half of one per cent. This has been attained in engines tested by the writer, and may be attained by careful manipulation of the best high-speed engines of almost any well-known makers. This solves the second of the prime requi-

sites—the first from the point of view of application, perhaps—that of exact regulation. No system of electric lighting can be satisfactory in which the fluctuation of speed of engine can be observed at the lamp, in its varying intensity. Such fluctuation cannot be perceived where restricted to a fraction of one per cent., nor can it practically interfere with good work when kept well under two per cent., the once accepted limit.

Economy comes in as a third requirement of the new type of engine. The older "simple" engines were expected to give the horse-power on an expenditure of not more than three pounds of good coal per hour, if non-condensing, and about two pounds if condensing; which corresponded to about twenty-five or seven pounds of steam for the first, and perhaps twenty pounds for the second class, with the best modern boilers, economisers, and heaters. But the older types of engine had a great advantage in their admirable systems of valve gearing which gave an equally excellent steam distribution; the separate steam and exhaust valves, separated ports, and quick cut-off all conspiring to enable the engineer to secure the closest possible approximation to the perfect ideal which is essential to maximum efficiency. The use of a single valve, in the high-speed engine, restricts him very seriously, and compels a certain loss of efficiency. From 30 to 50 per cent. more steam was thus at first used in these engines. Good proportions of valve and of gearing, amply high speed of rotation—itsself an element of economy—and practically frictionless and "isochronous" governors were brought out; but the machine still remained a less economical heat engine than the older type, and in most instances, seriously so. The source of this waste and the methods of its prevention were promptly made the subjects of investigation, and the wonderful inventive faculty of the American engineer was set at work to devise improvements.

The cause of waste was very quickly detected in the large amount of "internal condensation" or "cylinder condensation," as it has come to be called, which was consequent upon the high heat-conducting power of the metal of which the cylinder is composed, and the exaggeration of this loss which comes from the increased proportion of surface exposed to weight of steam passed through the engine, as sizes are diminished. The increased speed of engine had diminished its size for a given power, and this had, in turn, with the less effective steam distribution, produced a large percentage of waste. The amount of this loss varies, in ordinary good practice, from about 25 or 30 per cent. in an engine of about 200 I.H.P., to 40 or 50 per cent. with engines of 50 H.P. of the same make, and to 60 or 70 per cent. in engines of from 1 to 5 H.P.\* The remedies previously found effective in the prevention of waste were, however, well understood, and were promptly put into practice by the more enterprising builders. These are three in number: 1. Increasing the work of the engine in such manner that the amount of condensation in the unit of time being given, its proportion to the quantity of steam used in the engine in the same time should be reduced. 2. Superheating the steam, thus reducing its capacity for wasting heat in the engine. 3. Compounding the engine so that the waste of the one cylinder might be utilised in supplying the demand due to waste in the succeeding cylinder.

The first of these methods had been found effective, but the new engine was precluded from resort to this expedient from the fact that it was already constructed for as high speed as was found practically safe and satisfactory. The second device was known to be effective; but, while every builder endeavoured to secure dry steam, with more or less success and without meeting with serious embarrassment, the attempt to use superheated steam had been shown, by many years of experience, to be invariably attended with more or less risk to boilers and engine, and with considerably enhanced cost of maintenance. On the

\* Stationary Engines for Electric Lighting. By R. H. Thurston. New York: J. Wiley and Sons. 1890. (New edition.)

\* Philosophy of the Compound Engine; Trans. Am. Society of Mechanical Engineers, 1889; Journal Franklin Institute, December, 1889.

whole, superheating had never become a successful and accepted method of increasing economy, though well known to be in theory and in practice a most efficient means of reducing these internal wastes. A half century of experimental use, under all known conditions, had not given it permanent place among the standard expedients for securing maximum economy of steam and of fuel, even though endorsed by the highest of European authorities, M. Hirn. A few great designers and builders, as Corliss and Leavitt in this country, and Cowper and a few others in Great Britain and on the continent of Europe, had, in special cases—usually in steam pumping engines—made good use of the device; but these instances were rare, and the system was, and is, but slowly gaining ground.

Compounding, on the other hand, had been practiced from the days of Hornblower, the rival of Watt. At first entirely unsuccessful, the gradual rise of steam pressures, the gradual increase of the ratio of expansion, and the continually increasing demand for economy in use of fuel and of steam, gave this system a stronger hold as the years went by, and it at last became, a generation ago, a somewhat common method of construction of large engines for important work, and has now become the universal system in marine engineering, and in some departments of stationary engine building, as in pumping engines and the finer class of mill engines of large power. It was not quite understood, however, until recently, by the average practitioner, what were the real causes of its efficiency, and it was not known whether it would pay to employ it in small engines. This last doubt was promptly removed upon trying it, and the "high speed compound engine" is rapidly becoming the standard engine for its special field of work. It was found that the total gain in the best constructions, due to compounding, amounted to something like one-third on engines of large power, and often to one-half with the smaller sizes. This made the difference between success and failure, in many cases, and with a handsome margin on the right side. Nearly all builders promptly took up the system, after the first experimenters had gone ahead.

So far as now known, there are but two ways in which further improvements can be effected. The speed is at a limit beyond which it is expected to go but slowly as methods of construction are improved, and as the attendants become accustomed to management of the new engine; the regulation is as near perfection in the best engines as is either desired or expected; and simplicity of construction can hardly be carried further; indeed, the symptoms are rather that we may see a reaction in the direction of a multi-valve distribution in some cases.

The economical use of steam is still far from that indicated by theory as the ultimate. The engine above referred to demanding from 25 to 70 lbs. of steam per H.P. per hour, as actually built in the various sizes specified, should, if the ideal conditions could be attained, give its power at the rate of less than 18 lbs. The best engines built to-day, of any type and of highest duty, have an ideal expenditure of about 8 or 9 lbs. of steam per H.P. hour, while they actually employ from 13 lbs. upward. The two ways in which these losses, of a third or more, can be further reduced, so far as now known, are increasing the temperature, and, perhaps, the pressure of the steam used, and the production of a non-conducting and non-radiating surface within the cylinder of the engine.

Superheating the steam was shown by Hirn to be the best and most philosophical method, provided it could be made practicable from the constructor's point of view. This has not yet been generally practiced, but it is not improbable that it may be done with good design and construction of the superheating apparatus and proper management of the engine. Its use would render the jacket superfluous, as it is known that the latter has no appreciable effect where the steam is kept dry in the cylinder. No wastes are left that it can affect. It would substitute for the disadvantages of the jacket, as a matter of construction, those of the superheating system. The latter have formerly been the

greater; but it does not follow that they will continue to be so. A good superheater, and a good cylinder lubricating system for high temperatures, would accomplish this end. These should certainly be within reach of the inventor and constructor.

The securing of non-conductivity of the internal heat-wasting surfaces of the cylinder would not seem absolutely beyond our reach. A century ago, Smeaton, the greatest engineer of his day, in part accomplished this result by the use of a sheathing of wood on his pistons and cylinder-heads. This cannot be done with the high pressures and temperatures of steam usual to-day; but other plans may prove feasible. Mr. C. E. Emery, many years ago, tried enamelling these surfaces and with enough success to show that the idea is a good one; though the enamels and coverings then available were not suitable for this purpose. The writer has found a method patented by him some time since similarly effective and possibly practicable, and doubtless other inventors will turn their attention to the problem, ultimately with complete success.\*

Could a material be found of sufficient strength and a good non-conductor, of which the steam cylinder could be made, this result would be reached, and the efficiency of fluid of the ideal engine would be practically attained.

Like the best engines of other types, the modern high-speed engine now seems to have been brought, in its best forms, to so perfect a condition that the range for further improvement is probably very narrow, and the gain still to be made must come slowly and painfully. In regulation and in simplicity of construction, in speed of rotation and in general adaptation to its special work, it is comparatively satisfactory. The further improvement must be in economy of its operation and maintenance. Greater efficiency of the working fluid will be gained, as in all other heat engines, by increasing the temperature of the steam; higher efficiency of the engine as a machine will follow more effective ways of reducing engine friction; but the compounding of the engine must be taken as the last large economical step in its improvement.

The problems now arising in its application are those which come to the engineer in all departments of his work. He must decide what efficiency he can afford to pay for in increased cost of engine; what size of engine he should adopt for a given amount of work; what size of "unit" of power he may best adopt in dividing up the work, if he is to divide it at all, among several engines, and what each subdivision of power should measure. In general, it is now well understood that the engine should be given a lower ratio of expansion than was formerly supposed economical under specified conditions.† The ratio should rarely, probably, be greater than three or four in simple non-condensing engines, and at less than 100 pounds pressure, or greater than six or seven in simple condensing engines. Compounding enables the engineer to design his engine with a view to expansion down to a terminal pressure—in the latter case of, perhaps, 10 pounds—economically.

The unit of power adopted is made the largest at which the engine can be continuously employed in its regular duties, and for some hours together. Every case, and especially in electric lighting, compels the designer to study the problem from many points of view, and to compute probable expenditures and minima of costs for a variety of possible arrangements,

\* My plan consists in dissolving the iron from the surface of the parts exposed to the action of steam, as the faces of the piston, the interior of the heads and the ports, by the use of acid, thus leaving a thin covering of reduced conductivity; which surface is then, if desired, filled with a still better non-conductor, as the resin of a drying oil, with which it may be saturated. The experiments of Prof. E. C. Carpenter and of Mr. P. M. Chamberlain, indicate that this may effect a saving of a large fraction of the now seemingly unavoidable interior wastes.—*Trans. Am. Society of Civil Engineers*, 1890 (*Cresson meeting*).

† For a study of this subject in somewhat wide relations, see papers on "The Several Efficiencies of the Steam Engine," *Trans. Am. Society Mechanical Engineers*, 1882, and *Journal Franklin Inst.*, 1882.

before he can finally safely decide just what system to employ or what type of engine is likely to prove best for the intended establishment and plant. Mr. Field's work at the Edison station in Brooklyn, and that of Mr. Henthorn in Providence, are good examples of this problem, carefully worked out, while the plans of the West End Company in Boston, and many of those produced by Mr. Sprague, illustrate the solution of similar problems in street railway work.

---

### OBITUARY.

---

**SAX, JULIUS, M.S.A., M.I.E.E.** Born in 1824, in Sagarre, Russia.—Mr. Sax was educated at Königsburg, and went to Hamburg in the year 1845, where he was apprenticed to the late Mr. Filby, optical instrument maker, of that town. Having served his apprenticeship, he went to Berlin, where he entered the telegraph establishment of Messrs. Siemens and Halske. He came to London in 1851, and worked with Mr. L. Oertling for four years, after which he started in business on his own account for the manufacture of instruments. Mr. Sax was employed by the late Prof. Graham, at that time Master of the Royal Mint, to construct automaton and other balances for use in the Mint. At the Great International Exhibition of 1862 he exhibited bullion and chemical balances, and obtain a prize medal for excellence of workmanship and accuracy. These balances were, on recommendation of Prof. Graham, purchased by the Government for the Mint of Hong-Kong. In 1863 Mr. Sax turned his attention to domestic telegraphy, &c., and in 1864 took out patents for a metallic fire alarm button, which would act as an ordinary call as well as a fire alarm; also indicators to be used with same and for other purposes. In 1869 Mr. Sax invented a form of magneto A B C telegraph (patented); in 1870 an improved mechanical recorder (patented); in 1872 an electric billiard marker (patented); in 1881 an electro-magnetic telephone (patented); an electric water gauge (patented); an electric tell-tale clock for watchmen, with a fire indicator combined; an electric vane; automatic system of electric call bells for fire stations, &c. (exclusively adopted by the Metropolitan Board of Works for all the stations of the Metropolitan Fire Brigade in London); a system of cell calls for police stations, prisons, &c., as prepared for and adopted by the Commissioners of the Metropolitan Police for use at all stations under their control; also an improved apparatus especially adapted for communicating between drivers and passengers in vehicles, &c. (patented); an electric apparatus for checking cash takings (patented); a perfected form of automatic fire alarm (patented). Mr. Sax has also made several improvements from time to time in electric bells and appliances for various purposes, and has been awarded eight prize medals for excellence of manufacture, &c. Death took place on the 21st August, 1890, at his residence, 108, Great Russell Street, Bloomsbury, London.

The business of electrical engineer and electric light contractor will be carried on by his sons, at 7, Ridgmount Street, Store Street, W.C.

---

**Pay Station Telephones.**—An American contemporary states that a trial of the new automatic recording telephone system is to be had in Brooklyn, N.Y., by the New York and New Jersey Telephone Company. The new device, which is simply on the drop-a-nickel-in-the-slot plan, is to be adopted at pay stations. When a person wishes to telephone at a distance, on ringing up central from the pay station he will be told to place the proper amount in the slot. He will not be connected with the office he wishes to telephone to until he does so.

### NOTES.

**A New Lamp.**—A new all night lamp has been placed before the American public, which contains but one set of carbon holders. The novel feature of the lamp consists in the use of two carbons, held above in a clamp of peculiar design, and a third beneath of special size and shape.

**Church Lighting in America.**—The first church lighted by electricity in America is a new Catholic church at Westboro.

**Investments in Electricity.**—It is said that \$300,000,000 are invested in electrical undertakings in America.

**Variation of Carbon Resistance.**—The contribution on page 249, from Mr. Tanner, who sent us such an interesting communication last week, is another example of the truth of the old saw that there is nothing new under the sun. It is clear that Munck showed very conclusively the variability of the resistance of carbon under pressure, a discovery which has been claimed for others of later date.

**Okonite.**—The New York *Electrical Engineer* of the 20th inst. contains an illustrated description of the Passaic, N.J., factory of the Okonite Company. Water-power is utilised for driving the machinery, but this economical motor will not, we imagine, be available in the English branch works, which are said to be planned after the American establishment, which turns out daily an enormous quantity of insulated wire.

**Electric Coal Mining Machinery.**—Mr. Foree Bain, of Chicago, has devoted much attention to this subject, and has recently patented a complete system of coal mining by electrically-operated machinery, which consists of an under-cutting machine with an overhead drill for drilling a hole in which to place the explosive charge. The hole is drilled and the under-cut made simultaneously by the same motor. In good coal, Mr. Bain's machine will cut a slot 3 feet wide, 4 inches high, and 6 feet under, within three minutes.

**Prison Lighting.**—The Western Electric Company has just completed the installation of 1,100 lamps at the House of Correction, Chicago. Not only had the malicious propensities of the prisoners to be provided for, but in dealing with thick walls and steel plates, difficulties in the way of construction were met with to a degree not usual in electric light fitting. The hygienic conditions now obtained are said to have had a marked influence for good upon the spirits of those incarcerated.

**Strike in America.**—The *employés* of the Westinghouse Electric Company at Pittsburg struck, on August 11th, for shorter hours. 1,200 men are thus thrown out of work.

**Fires Caused by Electricity.**—A Dalziel cablegram says:—It is stated that the fire losses at Boston, U.S., during the past year have been four times greater than in any year since 1872. To electricity alone is attributed the loss of nearly £200,000 worth of property during the last twelve months.

**Electric Drilling Machines.**—The Brooklyn Navy Yard has adopted drilling machines worked by electromotors. It is stated that the form is very compact and portable, and a great saving of time is obtained in consequence of their employment.

**Lighting of Leamington.**—As a means of supplying a never-failing subject for argument and discussion, the electric light at Leamington has proved a distinct success. The trouble now appears to be as to whether the light given is up to standard or not.

**Man Wants but Little, &c.**—A strike of engineers occurred on the White Line Electric Road at Dayton, O., for an advance of \$2 per day, and the removal of the recently appointed manager who was engaged to promote better discipline. The strikers grounded the wires, and refused to allow the cars to be run back to the power shed. We should think that the rise demanded should read per week, although an American exchange gives the item as above.

**Electric Transmission of Power.**—When shall we be able to boast of supplying current to electric motors in workshops on anything like even a moderate scale? In New York alone this is done in small units to the extent of nearly 1,500 H.P., and it is expected that in another year the supply will be doubled.

**Proposed Electric Lighting at Weybridge.**—The Laing, Wharton and Down Construction Syndicate, Limited, having decided to apply to the Board of Trade for a provisional order, enabling them to light the parish of Weybridge by electricity, Mr. Kite, solicitor to the syndicate, and Mr. Rutherford, engineer, attended a meeting of the Chertsey Rural Sanitary Authority last week, for the purpose of explaining the scheme. It was pointed out that the syndicate was already carrying out the electric lighting of the town of Weybridge, but the area now proposed would be more extensive than the district already lighted. In order to obviate the objection to overhead wires, the syndicate was endeavouring to arrange for underground mains, for which, however, it would be necessary to obtain the consent of the local authority. The syndicate would ask for a period of two years in which to arrange for the carrying into execution of this feature of their scheme. After some discussion the authority consented to the provisional order, subject to the overhead wires being removed within two years.

**Southampton Corporation and the Electric Light.**—Mr. James T. Hamilton, secretary of the Southampton Electric Light and Power Company, Limited, writing on the subject of the recent negotiations with the Corporation of Southampton, for the purchase of the licence acquired by them, states that the corporation first approached the company, and that the offer of concession was made with reluctance. If the directors had foreseen the waste of time and inconvenience which has been occasioned by the delay of the company in coming to a decision, the offer would never have been made.

**Electric Etching.**—The *Papier Zeitung*, of Berlin, announces that an important discovery has been lately made in the processes of etching and photogravure. The drawing is traced on a plate of zinc by either an artist or by photography, with any suitable etching ground. This plate, backed with asphaltum, is laid in a bath of dilute acid. It is then put in circuit with a dynamo, the other pole being placed in the acid. On the current passing, the acid attacks the metal with extraordinary rapidity. A few minutes are sufficient to bite the plate, the depth of the etching being under easy control.

**Electric Lighting in Spain.**—The Huelva Gas Company, whose headquarters are at Glasgow, has applied for powers to light the town by electricity. Public opinion is so decidedly against electrical monopolies, that the local authorities have consented to grant the petition only under the condition that the gas company gives up all claims as to priority, &c., and is willing to enter into competition with other electric lighting companies.

**The "Peral."**—Coincident with the notice that a new Italian submarine boat has undergone successful trials, it is reported that the Spanish submarine boat, the *Peral*, about which the Spanish journals indulged in premature rejoicings, has been abandoned, having proved a complete failure.

**Private Lighting on a Large Scale.**—Mr. Rockefeller of the American Standard Oil Trust, is said to have spent \$150,000 in electric illumination of his park and grounds on the Hudson River.

**Cable Testing.**—The incident in our last issue, connected with cable testing, which might be termed a new development of the "Hall effect," ought not to be without its advantages. We have often had occasion to draw attention to the tendency of the electrical engineers of the present day to ignore the experiences of old timers in the telegraphic world, which, perhaps, for the future will be deemed worthy of more consideration.

**Gay-Lussac.**—A statue to Gay-Lussac, by Millet, was inaugurated at Limoges on the 11th. Gay-Lussac was a member of the Academie, and at one time collaborator with Arago and Ampère. He was also "reporter" to the Academic Commission, to whom much of the modern theory of lightning conductors is due. He died in 1850, just after he had commenced to devote particular attention to electric telegraphy. According to one of his biographers, he remarked at the time that it was extremely annoying to have to go just as the fun was commencing; or, in his own words: "Il est véritablement fâcheux de s'en aller, car voilà que cela commence à devenir drôle."

**Alternating Current Experiment.**—The *India Rubber World* says the experiment was recently tried of sending an alternating current of 1,000 volts pressure through the submarine cable which connects the electrically lighted buoy off Robbin's Reef, New York harbour. The experiment was made to see if the cable would stand the stress without breaking down or developing a fault, and the result was entirely successful as far as the cable was concerned. There was no leakage and no injury to the cable. This cable is insulated with gutta percha and was made by the Bishop Gutta Percha Company. The same company also manufactured the cables which carry current for lighting the six buoys in Gedney's Channel.

**Electricity on Wigan Tramways.**—The Chairman of the Wigan Tramway Company, after visiting the electrical works of the North Metropolitan Tramway at Canning Town, has presented a report to his co-directors, which states that the system employed would not work well in Wigan, as it could not be relied on. The report complains that the information given in regard to depreciation was scanty.

**Death of an American Telegraphist.**—Mr. Jephtha H. Wade, one of the pioneers of American telegraphs, died a few days ago at Cleveland. At a time when the financial position of telegraph companies was low, Mr. Wade's company was earning good returns. He constructed the first line west of Buffalo, and covered the whole of Ohio and Illinois with his lines. The well-known "Wade insulator" was invented by him. He leaves a fortune of about five million dollars.

**Messrs. Drake and Gorham.**—We understand that Messrs. Drake and Gorham have found it necessary, owing to the steady increase of their business, to double the size of their existing offices and stores.

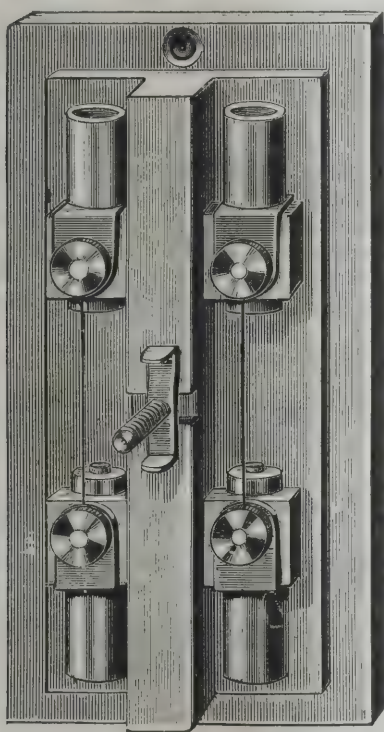

**Exportation of Para Rubber.**—During the first six months of 1890, says the *India Rubber World*, the United States absorbed 60 per cent. of the total exportations from Pará and Manáos, and about 70 per cent. of the shipments from Pará alone. A comparison of the quality of rubber imported by the United States, and by European countries from Pará, is shown in this table:—

	United States.	Europe.	Total.
Fina (fine) ... ..	5,750,716	4,541,919	10,292,635
Entrefina (medium) ...	1,140,757	877,263	2,018,020
Sernamby (coarse) ...	3,483,646	1,569,673	5,053,319
Caucho ... ..	702,831	353,014	1,055,845
Totals ... ..	11,077,950	7,341,868	18,419,818

**Elmore Shares.**—During the last fortnight a large rise has taken place in the price of Elmore shares, which are at present nearly £7. We also hear that negotiations are pending for the sale of several of the Foreign patents, the price of the Foreign company's shares being now nearly £9 per £5 share.

**The Stella Lamp.**—It seems that this lamp, a description of which appears on another page, is an old friend in a new guise. Mr. Desmond Fitzgerald could probably claim an intimate relationship with the Star which has suddenly appeared in the French Academy of Sciences.

**Binswanger's Patent Improved "H. I." Cut-Outs.**—Authorities on electric lighting have repeatedly dwelt upon the fact that the insulation resistance of electric light circuits suffer more from the fittings, switches, cut-outs, &c., used in the circuit, than from any other cause. In such cases, wire of a resistance of 300 or 600 megohms or more per mile has been used, and the leakage is traced entirely to the surface leakage of the china or slate at the back of the fittings. With a view to remedying these serious defects, the General Electric Company, Limited, has introduced a system of china fittings in which such leakage of the current is said

to be rendered impossible. The accompanying illustration shows a double-pole cut-out fitted in accordance with this patented system. The china is divided by a vertical wall, having four china blocks at its sides. To these china blocks are fitted the terminals for the wire, as also the screws for the cut-out. No screws or metal work appear at the back, and thus the leakage of current is obviated. This cut-out also has the advantage over those generally used that the fuse itself can be readily replaced. We understand that other fittings, such as switches, wall-plugs, ceiling roses, &c., are being manufactured by this company upon the same principle.

**The High Road to Success.**—The Brush Electrical Engineering Company, Limited, has entered into a contract with the London Road Car Company for the supply of 60 omnibuses for horse traction. These omnibuses will be constructed at the Brush Company's Falcon Works, Loughborough, where large extensions have been made to enable the company to cope with increasing demand for their steam engines, trams and omnibuses for electric or other traction, rolling stock, and electrical machinery, and apparatus of every description.

**Electricity and Advertising.**—Messrs. Pyke and Harris are adapting the use of vacuum tubes, in conjunction with Messrs. Pyke and Barnett's high-tension transformers, to the purposes of advertising, under the impression that letters or designs scintillating with the soft light of electric glow cannot fail to attract attention as much by their beauty as by their singular and entirely novel appearance.

**The New Spanish Cables.**—With regard to these cables, referred to in our issue of last week, the *Daily Telegraph* of August 25th contains the following announcement:—"The Foreign Office has issued the following: The Spanish Minister of the Interior, by a notice dated the 18th inst., has invited tenders for the construction and laying of telegraphic cables between Spain and the Spanish possessions on the north coast of Africa and to Tangier. Seven sections, of a total length of 332 miles, will be required. The maximum payment to the contractor will not exceed about £160 per mile. These tenders are to be addressed, in sealed covers, to the Director of Posts and Telegraphs, Telegraphic Department, No. 18, Calle de Claudio Coello, Madrid, and must be sent in within 30 days from the 18th inst. The conditions (in Spanish) may be seen at the Commercial Department of the Foreign Office, London, between the hours of eleven and five."

**Exhibition at Palermo.**—A National Exhibition will be held at Palermo next year. The committee has resolved to organise an electrical section in order to show the progress recently made in the various applications of electricity. It is proposed to make a larger display than those at the Milan and Turin exhibitions. The reasons why rapid development is taking place in Italy are the absence of gas works in many towns, the lack of a sufficient supply of coal, and the abundance of natural water power.

**Cable Laying.**—A very interesting article on cable laying appears in the *Cornhill Magazine* for September, a copy of which has been sent to us. It is not difficult to guess the quarter from whence it comes, and to those who desire to become acquainted, after half an hour's pleasant reading, with most of the operations connected with girdling the earth, we cordially recommend the paper.

**The Tory Island Cable.**—At noon, on August the 26th, the Duke and Duchess of Abercorn inaugurated the new signal and telegraph station on Tory Island. On approaching the island in the steamer *Thistle*, the Duchess threw overboard a floating box containing a number of telegrams, among them one addressed to the Queen, expressing congratulations on the establishment of telegraphic communication with the most westerly portion of Ireland.

**Probable Electric Lighting at Sheerness.**—The Sheerness Local Board of Health is considering the advisability of adopting the electric light for the town in place of gas, and has given instructions to their surveyor, Mr. W. W. Copland, to supply them, at their next meeting, with information on the subject.

**The Infant Dynamo.**—A memorandum from Messrs. Page and Miles, of Brighton, informs us that they have recently completed an electric light installation at Tudor House, Burgess Hill, the machine employed being an Austin "Infant" dynamo, 200 watts, shunt-wound, driven by a two-man gas engine, E.P.S. accumulators being used to regulate the current.

**Rashleigh Phipps and Dawson.**—Church lighting is making progress. Messrs. Rashleigh Phipps and Dawson have just received the order for a complete installation for the church of St. John the Divine, Kennington. The Royal Standard Music Hall, and St. Martin's-in-the-Fields Free Public Library, are also in the hands of the same firm.

**Personal.**—We referred in our issue of August 15th to the resignation by Mr. A. R. Bennett of his post of general manager to the National Telephone Company, Limited. We understand that differences with the directors was the cause. Since the amalgamation, last year, the operations of the extended National Company, which has nothing in common with the old National except the name, have been chiefly directed by gentlemen who were directors of the old United Telephone Company which worked London, and of the old Lancashire and Cheshire Company. Mr. Bennett, who had previously been unable to agree with the policy of the new board on several important points, determined, towards the end of July, on an event of an extraordinary nature occurring which showed cordial co-operation in the future to be hopeless, to sever his connection with the company at the earliest possible date—October 31st.

We understand that Mr. F. G. Thomas, of the Manchester Edison-Swan Company, Limited, has resigned his appointment as storekeeper of that company, and has left this country for Australia, where he will join the Williamson Electric Light Company of Sydney.

**The Bermudas-Halifax Cable.**—Messrs. Henley's telegraph cable ship *Westmeath*, lately engaged in the laying of the Bermuda-Halifax section, returned to the Thames on the 19th inst., having successfully completed the laying of the cable from Halifax, Nova Scotia, to the Bermudas. The expedition left the Thames on the 23rd May last, so that the whole work has been accomplished (including the guarantee period of 30 days) within three months. Eight soundings were taken near Bermuda in the main route of the cable, which showed a regular increase in depth from 24 to 1,240 fathoms, the steepest gradient found being about 1 in 4. Soundings taken on the Halifax side for the purpose of defining the slope of the bottom from the deep water up to the edge of the flat, which extends for nearly 100 miles outside Halifax, showed a regular decrease from 1,089 to 118 fathoms. The carrying out of this work reflects the greatest credit on Messrs. Henley's staff, it being well known that the laying of this cable presented exceptional difficulties, in fact, the strongest doubts have been expressed by authorities as to the possibility of laying such a cable successfully. We understand that the same vessel has been chartered by Henley's Telegraph Company for the laying, in the West Indies, of those cables which will form an extension southward of the system owned by the Société Française des Télégraphes Sous-Marins. As our readers are probably aware, the cables already laid on behalf of this company are:—

Aguadores (Cuba) to Caimanera (Cuba) ...	50 N.M.
Caimanera (Cuba) to Mole-St.-Nicolas (Hayti) ...	126 "
Mole-St.-Nicolas (Hayti) to Puerto Plata (St. Domingo) ...	188 "
St. Domingo (St. Domingo) to Curaçoa ...	453 "
Curaçoa to La Guayra (Venezuela) ...	163 "
	980 N.M.

**Newspaper Enterprise.**—The *Times* newspaper spent over £6,000 in telegraphing day-by-day the news of the revolution in Buenos Ayres.

**Electric Light Wanted in the Bermudas.**—A writer to a New York daily states that there are no electric lights on the islands, but that the principal inhabitants "want them badly." He mentions a dozen persons who would go to a heavy expense in order to have the electric light.

#### NEW COMPANIES REGISTERED.

**United Flexible Metallic Tubing Company, Limited.**—Capital, £75,000 in £10 shares. Objects: To amalgamate the Flexible Metallic Tubing Company, Limited,

and the Belgian and Colonial Flexible Metallic Tubing Company, Limited, and to carry on the business of mechanical engineers, electrical engineers and metallurgists. Signatories (with 1 share each): Claude Scott, 15, Arkwright Road, N.W.; R. Henderson, C.E., 8, Draper's Gardens; R. T. Hewlett, M.R.C.S., 28, Keppel Street, W.C.; A. H. Bacon, 30, Bridge Avenue, Hammersmith; J. W. Hewlett, 105, Bennerley Road, Wandsworth Common; S. Wade, 76, Santee Street, Clapham Common; J. D. Jones, 5, Ryde Terrace, Stockwell. The first directors are F. Walton, 4, Portugal Street, W.C.; G. Marsham, Maidstone; A. J. Thornton, 36, Rosary Gardens, S.W.; qualification, £250 in shares or stock; remuneration, chairman £200 per annum, each director £100 per annum. Registered 20th inst. by R. Hewlett, 31, Essex Street.

**Lamp Manufacturing Company, Limited.**—Capital, £16,000 divided into 1,000 preference shares of £10 each, 3,000 ordinary, and 3,000 deferred shares of £1 each. Objects: To adopt an agreement with the Redsdale Railway Lamp and Lighting Company, Limited, and its liquidator, Mr. Edward Cecil Moore. To manufacture lamps of all kinds, and apparatus for the consumption and supply of gas, oil, and electricity. To carry on business as mechanical, gas, and electrical engineers. To produce and supply gas, oil, electricity, or electrical currents or force, for light, heat, motive power, or force. Signatories (with 1 ordinary share each): W. W. Paine, 14, St. Helen's Place; J. J. Collins, 45, City Road; P. E. Chalhon, 18, Saltoun Road, Brixton; C. R. Pearson, 2, Balfour Terrace, Leytonstone; J. E. Wood, Dexter House, East Dulwich; R. Sutton Clarke, 132, Westbourne Terrace; C. J. Harper, 39, Leighton Grove, N.W. The signatories are to appoint the first directors; qualification, £50 in shares; remuneration, chairman, £3 3s.; each director £2 2s. for every meeting attended. Registered 26th inst. by Paine, Son and Pollock, 14, St. Helen's Place, E.C.

#### OFFICIAL RETURNS OF ELECTRICAL COMPANIES.

**Vaughan-Sherrin Electrical Engineering Company, Limited.**—An agreement of 11th inst. provides for the purchase by the company of the following letters patent from John Vaughan-Sherrin, of 19, Duncan Terrace, Islington, N., viz.:—No. 15,730, 1887; 20, 1888; 2,666, 1888; 5,390, 1888; 12,455, 1888; 13,473; 10,647, 1889. Patents applied for:—17,831, 1889; 4,767, 1890. Foreign patents:—19,2907 (French), 1888; 83,228 (Belgian), 1888. The purchase consideration is £3,000 in cash, fully-paid founders' shares, and fully-paid ordinary shares, equal to the number otherwise allotted, so that the vendor and his nominees shall hold one-half of the shares of the company.

The registered office of this company is at 48, Eagle Wharf Road, Hoxton.

**Northern Electric Wire and Cable Manufacturing Company, Limited.**—An order of the Chancery Division of the High Court of Justice, dated 17th ult. and filed 18th inst., directs the striking out of the name of Edward William Hall, of Park House, Bradford, from the register of shareholders, as a holder of 160 shares. It is also ordered that the sum of £80 paid by him upon his application for shares be forfeited, together with interest thereon at the rate of 4 per cent. per annum from 4th July, 1889, to the date of repayment, and also the costs of his application to the Court, to be taxed by the taxing master.

The annual return of this company is made up to the 4th March. The nominal capital is £20,000, divided into 660 fully-paid up vendors' shares and 3,340 ordinary shares of £5 each. Upon the latter £1 10s. per share has been called, the calls paid amounting to £945 10s., and unpaid to £17 10s. The sum of £80 has been paid upon 160 shares forfeited since the return of the 12th November, 1889.

**Baxters, Limited** (general mechanical, marine and electrical engineers).—At an extraordinary general meeting of the members of this company, held at the registered offices, Sandiacre, near Nottingham, on the 15th ult., it was resolved that the directors may, notwithstanding any rule of law or equity to the contrary, contract on behalf of the company for the purchase from four of their number, viz.: S. Pryer Baxter, Frederick Baxter, A. N. Baxter, and C. H. Baxter, the goodwill and assets of their business at Sandiacre, at the price of £19,950, and which purchase may date from 1st June last. The resolution was confirmed on the 31st ult., and duly filed 1st inst.

**Beales, Limited** (confectionery and electricity).—At an extraordinary general meeting of this company, held at 370, Holloway Road, on the 14th ult., it was resolved to wind up voluntarily, Mr. H. S. Shipton, of Ellendale, Crescent Road, Crouch End, being appointed liquidator. The resolution was confirmed 31st ult., and duly filed 2nd inst.

**Head, Wrightson and Company, Limited** (engineers and bridge and pier builders, and electricians).—An agreement of 24th June, filed 2nd ult., provides for the purchase of the business of this firm, carried on at South Shields. The purchase consideration is £310,000, payable £240,005 in cash, and the residue in fully paid shares.

**John Wright and Company, Limited** (gas, electrical and general engineers).—An agreement of 26th June, filed 11th inst., provides for the purchase of the business of the firm of John Wright & Co., of the Essex Works, Aston Junction, Birmingham, for £85,183, payable £49,183 in cash, and the residue by the allotment of 100 debentures of £100 each, 2,600 preference shares of £5 each, and 2,600 ordinary shares of £5 each.

**Elmore's Wire Manufacturing Company, Limited.**—The following resolution, passed at an extraordinary general meeting, held at Cannon Street Hotel on the 14th ult., was confirmed at a meeting held at 20, Bucklersbury, on the 6th inst., and was duly filed on the 18th inst., viz.:—"That the following clause be substituted for Clause 80 of the articles of association: 'The company may make contracts with any of the directors upon such terms as the directors shall think fit, and a director shall not, by reason of the fiduciary relation subsisting between him and the company, be accountable for any profits made by him in respect of any such contract, nor, subject to the following proviso, in respect of any other contract made with the company in the profits of which he participates, or in which he is otherwise interested; provided that the fact of his being so interested therein, and the nature of his interest, be fully and fairly disclosed by him at the meeting of directors at which the contract is determined on, if his interest then exists, or in any other case at the first meeting of the directors after the acquisition of his interests; but, in the case of contracts with companies or firms of which any director of the company is a member, it shall not be necessary to disclose more than the fact of such membership, provided always that in no case shall such director so interested vote, or, if he does vote, his vote shall not be counted.'"

**Elmore's Patent Copper-Depositing Company, Limited.**—The annual return of this company, made up to the 11th August, was filed on the 18th inst. The nominal capital is £200,000 in £2 shares; 70,000 shares are taken up, and of these 23,300 are considered as fully paid up. Upon 46,700 shares the full amount has been called and paid, the paid up capital thus being £93,400. The sum of £7 18s. has been received upon 15 shares forfeited.

**Edison and Swan United Electric Light Company, Limited.**—The annual return of this company, made up to the 13th inst., was filed on the 21st inst. The nominal capital is £1,000,000, divided into 150,000 "A" and 50,000 "B" shares, of £5 each. The shares taken up are 89,261 "A," upon which 10s. per share has been

called, 17,139 "A," considered as fully paid, 23,564 "B," considered as fully paid. The calls paid amount to £223,152 10s.

**Plymouth and District Pulsion Telephone Company, Limited.**—An agreement of 13th inst., filed 20th inst., provides for the purchase by the company from the Primary Sydicate, Limited, of a licence to use the letters patent No. 8,457, dated 9th June, 1888, granted to Lemuel Mellett for improvements in mechanical telephones. The purchase consideration is £3,100, payable £100 in founders' shares and £3,000 in ordinary shares, all fully paid.

**Sheffield Telephone Exchange and Electric Light Company, Limited.**—The annual return of this company, made up to the 20th inst., was filed on the 28th inst. The nominal capital is £60,000 in £10 shares, the whole of which are taken up. Upon 923 shares the sum of £8 per share has been called. There has been called on 3,077 shares an aggregate sum of £10,770, being the balance due on the said shares after deducting the £7,692 considered as calls paid. The calls paid amount to £17,988, and unpaid to £166, and £33,846 is considered as paid upon 5,077 shares.

**City of Westminster Electrical Syndicate, Limited.**—The annual return of this company, made up to the 13th inst., was filed on the 20th inst. The nominal capital is £20,000, divided into 10,000 shares of £1 each, and 1,000 shares of £10 each. The whole of the £1 shares have been taken up, and the full amount has been paid thereon.

**Parker's Electric Wire Corporation, Limited.**—A meeting of this company was held on the 12th inst., when an account was given as to the manner in which the winding up of the company has been conducted, and its property disposed of.

**Consolidated Telephone Construction and Maintenance Company, Limited.**—The annual return of this company, made up to the 12th June, was filed on the 20th inst. The nominal capital is £307,545, divided into 75,000 6 per cent. preference shares of £1 each, 224,850 ordinary shares of 14s. each, and 75,150 ordinary shares of £1 each. The shares taken up are 25,000 preference and 224,850 ordinary shares. Upon each preference share £1 has been paid, and upon each ordinary share 14s. The calls paid amount to £182,395.

---

## CITY NOTES.

---

**The West Metropolitan Tramways Company.**—At the meeting of this company, held this week, the chairman, Mr. E. H. Bayley, in the course of his remarks on the position of the company, referred to the action of the various local authorities through whose district the company's line ran, and quoted from the remarks from Mr. Webb, their solicitor, at the last meeting on the question of electrical traction. Negotiations had been in progress in respect to this matter for several months, but eventually the electrical company withdrew their proposal. It was satisfactory, however, that fresh negotiations were in progress with another electrical company, who offered to undertake the work on advantageous terms as soon as the local authorities should have given their sanction. He moved the adoption of the report. Mr. J. W. Greig seconded, and his motion was carried. The proceedings terminated with a vote of thanks to the chairman.

**The Electric Construction Corporation, Limited.**—The Committee of the Stock Exchange has ordered shares Nos. 101 to 45,100 of the corporation, to be quoted in the official list.

**The Petroleum Engine Company, Limited.**—A meeting of shareholders was held at the company's offices, 23, Queen Victoria Street, E.C. The proceedings were not open to the press.

---

## TRAFFIC RECEIPTS.

---

The Brazilian Submarine Telegraph Company, Limited. The traffic receipts for the week ending August 22nd, were £5,121.

The Western and Brazilian Telegraph Company, Limited. The receipts for the week ending August 22nd, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, Limited, were £3,99.

THE SANITARY ASPECTS OF ELECTRIC LIGHTING.\*

By W. H. PREECE, F.R.S.

THE chief tendency of modern legislation in our British Parliament is to improve the environments of the human frame, so that we may live, and move, and have our being with greater health to the individual, and greater prosperity to the nation. The cleanliness of dwellings, the drainage of towns, the removal of filth, the suppression of nuisances, have not only been specified but the inspection of the means to effect these objects, and of their results, are defined and insisted upon by Acts of Parliament. People often speak disrespectfully of our grandmotherly Government, but at least in this region of domestic legislation, the control it has exercised over the food we eat, the water we drink, the air we breathe, is of a true parental order, and deserves our unreserved admiration and respect. The Home Office and the Local Government Board act the part of a wise and economic head of the house to the nation, while each community has its own Local Board or Authority to carry out hygienic provisions, to enforce sanitary principles, to prevent infection, to stamp out disease, to sweeten labour, and to prolong life.

I contemplated at one time submitting an historical summary of these features of sanitary legislation during the present generation, but not only would the task be very onerous, but it would be so lengthy that I should have very little time left to discuss the question set before me—the sanitary aspects of electric lighting.

The propositions that I propose to submit and to demonstrate to you are these:—

1. That electricity and light being analogous and identical forms of energy, the former is naturally the proper source of artificial illumination.
2. That all other sources of artificial illumination being dependent on the absorption of oxygen, and resulting in the vitiation of air are injurious to health.
3. That the same authority which regulates the sanitation of our dwellings, and the supply of our food, should also control the purity of the air we breathe, and of the light we work by.

Light, however it be produced artificially, is simply the equivalent of work that has been done elsewhere. Whether it be by the combustion of tallow or oil, by the burning of coal or of gas, by the glowing of a fine wire, or the formation of the brilliant arc, energy has been expended somewhere, to be transferred and reproduced in some other place in the form of light. The great principle of the conservation of energy teaches us that the amount of energy in the universe is a fixed quantity, that it can be neither created nor destroyed, that it can only be transferred, and that any expenditure of energy—work done—anywhere is the equivalent of energy utilised somewhere else. The rate at which this energy is expended is called *power*, and the amount of power which we foolishly call a *horse-power*, and which we roughly imagine to be equivalent to the power exerted by a horse in drawing a load along a road, is competent to produce an amount of light which is very simply measured. Our standard of light is the light given by a No. 6 sperm candle, burning 120 grains per hour. Now the energy of one horse-power constantly expended will give by the aid of

Tallow ... ..	the light of 6 candles
Sperm ... ..	8.7 "
Oil... ..	9 "
Gas ... ..	13 "
Electric current—Glow	248 "
" Arc	1,492 "

The results to the air of these different modes of producing artificial illumination are well shown by the following table:—

Products of Combustion in developing 100 candles per hour.

Illuminant.	Quantity Consumed.	Carbonic Acid produced.	Water Vapour.	Heat.
	lbs.	cub. ft.	lb.	Calories.
Tallow .....	2.2	51.2	2.3	9,700
Sperm .....	1.7	41.3	2.0	7,960
Oil .....	1.3	33.6	1.8	7,200
Gas .....	56 cub. ft.	40.3	2.5	12,150
Electricity .....	(Coal) 2.2 lbs.	0	0	257

Thus we see how very much more efficient electricity is than any other agent for the production of light.

The great hygienic advantage of the electric light when illuminating our dwellings and our workshops, is not that it purifies the air, but that it prevents the air from being vitiated by the introduction into it of the products of combustion, such as carbonic acid, carbonic oxide, sulphurous oxide, &c.; it prevents the air from being weakened by the abstraction of oxygen, and it prevents it from having its temperature raised by undue radiation; and by throwing into it heated gases.

While legislation and the greatest possible stringent regula-
